Review for Exam 1.

- ▶ 5 to 7 problems.
- ► No multiple choice questions.
- ▶ No notes, no books, no calculators, no phones.
- Problems similar to homeworks, webwork.
- Exam covers:
 - ► Linear equations (1.1), (1.2).
 - ▶ Bernoulli equation (1.2).
 - Separable equations (1.3).
 - Euler homogeneous equations (1.3).
 - Exact equations (1.4).
 - Exact equations with integrating factors (1.4).
 - ► Applications (1.5).

Exam overview

Remark:

- Exam problems will be: Solve this equation. We don't tell you if the equation is linear, separable, etc. You must find that out.
- If you know what type of equation is, then the equation is simple to solve.
- The difficult part in Exam 1 is to know what type of equation is the one you have to solve.

Example

Find every solution y to the equation $(t^2 + y^2)(t + yy') + 2 = 0$.

Solution: Rewrite the equation in a more standard way:

$$(t^2+y^2)y\,y'+(t^2+y^2)t+2=0 \quad \Leftrightarrow \quad y'=-rac{(t^2+y^2)t+2}{(t^2+y^2)y}.$$

Not linear. Not Bernoulli. Not Separable. Not Euler homogeneous. So the equation must be exact or exact with integrating factor.

$$N = t^2 y + y^3 \Rightarrow \partial_t N = 2ty.$$

 $M = t^3 + ty^2 + 2 \Rightarrow \partial_y M = 2ty$

The equation is exact: $\partial_t N = \partial_y M$.

Example

Find every solution y to the equation $(t^2 + y^2)(t + y y') + 2 = 0$. Solution: $\partial_t N = \partial_y M$, $[(t^2 + y^2)y]y' + [(t^2 + y^2)t + 2] = 0$. There exits a potential function ψ such that $\partial_y \psi = N$, $\partial_t \psi = M$.

$$\partial_{y}\psi = t^{2}y + y^{3} \implies \psi = t^{2}\frac{y^{2}}{2} + \frac{y^{4}}{4} + g(t).$$

$$ty^{2} + g'(t) = \partial_{t}\psi = M = t^{3} + ty^{2} + 2.$$

$$g'(t) = t^{3} + 2 \implies g(t) = \frac{t^{4}}{4} + 2t.$$

$$\psi(t, y) = \frac{1}{2}t^{2}y^{2} + \frac{y^{4}}{4} + \frac{t^{4}}{4} + 2t, \qquad \psi(t, y(t)) = c. \qquad \triangleleft$$

Review Exam 1.

Example

Find the explicit solution y to the IVP

$$y' = rac{t(t^2 + e^t)}{4y^3}, \qquad y(0) = -\sqrt{2}.$$

Solution: Not linear. Bernoulli with n = -3. Numerator depends only on *t*, denominator depends only on *y*: Separable.

$$4y^3 y' = t^3 + te^t \quad \Rightarrow \quad \int 4y^3 y' \, dt = \int (t^3 + te^t) \, dt + c$$

The usual substitution: u = y(t) implies du = y'(t) dt,

$$\int 4u^3 du = \int (t^3 + te^t) dt + c \quad \Rightarrow \quad u^4 = \frac{t^4}{4} + \int te^t dt + c.$$

Example

Find the explicit solution y to the IVP

$$y' = rac{t(t^2 + e^t)}{4y^3}, \qquad y(0) = -\sqrt{2}.$$

Solution: Recall: $u^4 = \frac{t^4}{4} + \int te^t dt + c$. Integration by parts:

$$\begin{cases} f = t, & g' = e^t, \\ f' = 1, & g = e^t, \end{cases} \Rightarrow \int te^t dt = te^t - \int e^t dt = (t-1)e^t.$$

We obtain: $y^4(t) = \frac{t^4}{4} + (t-1)e^t + c$. The initial condition:

$$\left(-\sqrt{2}\right)^4 = 0 + (0-1) + c \quad \Rightarrow \quad 4 = -1 + c \quad \Rightarrow \quad c = 5$$

We conclude: $y^4(t) = \frac{t^4}{4} + (t-1)e^t + 5$. Implicit form.

Review Exam 1.

Example

Find the explicit solution y to the IVP

$$y' = rac{t(t^2 + e^t)}{4y^3}, \qquad y(0) = -\sqrt{2}.$$

Solution: Recall: $y^4(t) = \frac{t^4}{4} + (t-1)e^t + 5$. Implicit form.

The explicit form of the solution is one of:

$$y(t) = \pm \left[\frac{t^4}{4} + (t-1)e^t + 5\right]^{1/4}$$

The initial condition implies $y(0) = -\sqrt{2} < 0$.

We conclude that the unique solution to the IVP is

$$y(t) = -\left[\frac{t^4}{4} + (t-1)e^t + 5\right]^{1/4}.$$

Example

Find every solution y of the equation $y' = \frac{3y^2 - t^2}{2ty}$.

Solution: Not linear. Bernoulli n = -1: $y' = \frac{3y}{2t} - \frac{t}{2y}$. Not separable. Every term on the right hand side is of the form $t^n y^m$ with n + m = 2. Euler homogeneous.

$$y' = \frac{3y^2 - t^2}{2ty} \frac{\left(\frac{1}{t^2}\right)}{\left(\frac{1}{t^2}\right)} \quad \Rightarrow \quad y' = \frac{3\left(\frac{y}{t}\right)^2 - 1}{2\left(\frac{y}{t}\right)}.$$

We introduce the change of unknown:

$$v = rac{y}{t} \quad \Rightarrow \quad y = t \, v \quad \Rightarrow \quad y' = v + t \, v'.$$

Review Exam 1.

Example

Find every solution y of the equation $y' = \frac{3y^2 - t^2}{2ty}$.

Solution:
$$y' = \frac{3\left(\frac{y}{t}\right)^2 - 1}{2\left(\frac{y}{t}\right)}, \quad v = \frac{y}{t}, \quad y' = v + t v'.$$

 $v + t v' = \frac{3v^2 - 1}{2v} \quad \Rightarrow \quad t v' = \frac{3v^2 - 1}{2v} - v = \frac{3v^2 - 1 - 2v^2}{2v}$
 $t v' = \frac{v^2 - 1}{2v} \quad \Rightarrow \quad \frac{2v}{v^2 - 1} v' = \frac{1}{t}.$
This is a separable equation for $v: \int \frac{2v}{v^2 - 1} v' dt = \int \frac{1}{t} dt + c.$

Example

Find every solution y of the equation $y' = \frac{3y^2 - t^2}{2ty}$.

Solution: $\int \frac{2v}{v^2 - 1} v' dt = \int \frac{1}{t} dt + c.$ The substitution $u = v^2 - 1$ implies du = 2v v' dt. So, $\int \frac{du}{u} = \int \frac{1}{t} dt + c \quad \Rightarrow \quad \ln(|u|) = \ln(|t|) + c \quad \Rightarrow \quad |u| = c_1 |t|.$ where $c_1 = e^c$. Substitute back: $|v^2 - 1| = c_1 |t|$. Finally, v = y/t, $\left| \frac{y^2}{t^2} - 1 \right| = c_1 |t| \quad \Rightarrow \quad |y^2 - t^2| = c_1 |t|^3.$

Review Exam 1.

Example

A water tank initially has $V_0 = 100$ liters of water with Q_0 grams of salt. At $t_0 = 0$ fresh water is poured into the tank. The salt in the tank is always well mixed. Find the rates r_i and r_o such that:

- (a) The tank water volume is constant.
- (b) The time to reduce the salt in the tank to one percent of the initial value is $t_1 = 25$ min.

Solution:

Part (a): Water volume constant implies $r_i = r_o = r$. Then V'(t) = 0, so $V(t) = V_0$.

Part (b): First find the salt in the tank Q(t): $\frac{dQ}{dt} = r_i q_i - r_o q_o(t)$. Incoming fresh water: $q_i = 0$. Mixing: $q_o(t) = Q(t)/V(t)$.

$$rac{dQ}{dt} = -rac{r}{V_0} Q(t) \quad \Rightarrow \quad Q(t) = Q_0 \, e^{-rt/V_0}.$$

Example

A water tank initially has $V_0 = 100$ liters of water with Q_0 grams of salt. At $t_0 = 0$ fresh water is poured into the tank. The salt in the tank is always well mixed. Find the rates r_i and r_o such that:

- (a) The tank water volume is constant.
- (b) The time to reduce the salt in the tank to one percent of the initial value is $t_1 = 25$ min.

Solution: Recall: $Q(t) = Q_0 e^{-rt/V_0}$. Condition for r:

$$Q(t_1) = \frac{Q_0}{100} \Rightarrow Q_0 e^{(-rt_1/V_0)} = \frac{Q_0}{100} \Rightarrow -\frac{rt_1}{V_0} = \ln\left(\frac{1}{100}\right).$$
$$\frac{rt_1}{V_0} = \ln(100) \Rightarrow r = \frac{V_0}{t_1} \ln(100) \Rightarrow r = 4 \ln(100).$$

Review Exam 1.

Example

Find the solution y to the IVP

$$y' = rac{2}{t}y - rac{\sin(t)}{t}y^2, \qquad y(2\pi) = 2\pi, \qquad t > 0.$$

Solution: Not linear. Bernoulli for n = 2. Divide by y^2 .

$$\frac{y'}{y^2} - \frac{2}{t}\frac{1}{y} = -\frac{\sin(t)}{t}, \qquad v = \frac{1}{y} \quad \Rightarrow \quad v' = -\frac{y'}{y^2},$$
$$-v' - \frac{2}{t}v = -\frac{\sin(t)}{t} \quad \Rightarrow \quad v' + \frac{2}{t}v = \frac{\sin(t)}{t}.$$

We solve the linear equation with the integrating factor method.

$$A(t) = \int rac{2}{t} dt = 2 \ln(t) = \ln(t^2) \quad \Rightarrow \quad \mu(t) = t^2$$

Example

Find the solution y to the IVP

$$y' = rac{2}{t}y - rac{\sin(t)}{t}y^2, \qquad y(2\pi) = 2\pi, \qquad t > 0.$$

Solution: Recall: $\mu(t) = t^2$. Then,

$$t^2\left(v'+\frac{2}{t}v\right)=t^2\frac{\sin(t)}{t}$$
 \Rightarrow $(t^2v)'=t\sin(t).$

Integrating: $t^2 v = \int t \sin(t) dt + c$. The right hand side can be computed integrating by parts,

$$\int t\sin(t) dt = -t\cos(t) + \int \cos(t) dt, \quad \left\{ egin{array}{c} f = t, & g' = \sin(t), \ f' = 1, & g = -\cos(t). \end{array}
ight.$$

Review Exam 1.

Example

Find the solution y to the IVP

$$y' = rac{2}{t}y - rac{\sin(t)}{t}y^2, \qquad y(2\pi) = 2\pi, \qquad t > 0.$$

Solution: $\int t \sin(t) dt = -t \cos(t) + \int \cos(t) dt$. Then,

$$t^2 v = -t\cos(t) + \sin(t) + c \quad \Rightarrow \quad t^2 \frac{1}{y} = -t\cos(t) + \sin(t) + c.$$

The initial condition: $4\pi^2 \frac{1}{2\pi} = -2\pi \cos(2\pi) + 0 + c$, so $c = 4\pi$.

$$y = \frac{t^2}{\sin(t) - t\cos(t) + 4\pi} \qquad \lhd$$

Example

Find the integrating factor that converts the equation below into an exact equation, where

$$\left(x^{3}e^{y}+\frac{x}{y}\right)y'+(2x^{2}e^{y}+1)=0.$$

Solution: We first verify if the equation is not exact.

$$N = \left(x^3 e^y + \frac{x}{y}\right) \quad \Rightarrow \quad \partial_x N = 3x^2 e^y + \frac{1}{y}$$

$$M = (2x^2e^y + 1) = 0 \quad \Rightarrow \quad \partial_y M = 2x^2e^y.$$

So the equation is not exact. We now compute

$$\frac{\partial_{y}M - \partial_{x}N}{N} = \frac{2x^{2}e^{y} - \left(3x^{2}e^{y} + \frac{1}{y}\right)}{\left(x^{3}e^{y} + \frac{x}{y}\right)} = \frac{-x^{2}e^{y} - \frac{1}{y}}{x\left(x^{2}e^{y} + \frac{1}{y}\right)} = -\frac{1}{x}.$$

Review Exam 1.

Example

Find the integrating factor that converts the equation below into an exact equation, where

$$\left(x^{3}e^{y}+\frac{x}{y}\right)y'+(2x^{2}e^{y}+1)=0.$$

Solution: Recall: $\frac{\partial_y M - \partial_x N}{N} = -\frac{1}{x}$. Therefore,

$$\frac{\mu'(x)}{\mu(x)} = -\frac{1}{x} \quad \Rightarrow \quad \ln(\mu) = -\ln(x) = \ln\left(\frac{1}{x}\right) \quad \Rightarrow \quad \mu(x) = \frac{1}{x}.$$

So the equation $\left(x^2e^y+\frac{1}{y}\right)y'+\left(2xe^y+\frac{1}{x}\right)=0$ is exact. Indeed,

$$\begin{split} \tilde{N} &= \left(x^2 e^y + \frac{1}{y} \right) \quad \Rightarrow \quad \partial_x \tilde{N} = 2x e^y, \\ \tilde{M} &= \left(2x e^y + \frac{1}{x} \right) \quad \Rightarrow \quad \partial_y \tilde{M} = 2x e^y, \end{split} \qquad \Rightarrow \quad \partial_x \tilde{N} = \partial_y \tilde{M}. \end{split}$$

Example

Find the integrating factor that converts the equation below into an exact equation, where

$$\left(x^{3}e^{y}+\frac{x}{y}\right)y'+(2x^{2}e^{y}+1)=0.$$

Solution: We first verify if the equation is not exact.

$$N = \left(x^3 e^y + \frac{x}{y}\right) \quad \Rightarrow \quad \partial_x N = 3x^2 e^y + \frac{1}{y}$$

$$M = (2x^2e^y + 1) = 0 \quad \Rightarrow \quad \partial_y M = 2x^2e^y$$

So the equation is not exact. We now compute

$$\frac{\partial_{y}M - \partial_{x}N}{N} = \frac{2x^{2}e^{y} - \left(3x^{2}e^{y} + \frac{1}{y}\right)}{\left(x^{3}e^{y} + \frac{x}{y}\right)} = \frac{-x^{2}e^{y} - \frac{1}{y}}{x\left(x^{2}e^{y} + \frac{1}{y}\right)} = -\frac{1}{x}.$$

Review Exam 1.

Example

Find the integrating factor that converts the equation below into an exact equation, where

$$\left(x^{3}e^{y}+\frac{x}{y}\right)y'+(2x^{2}e^{y}+1)=0.$$

Solution: Recall: $\frac{\partial_y M - \partial_x N}{N} = -\frac{1}{x}$. Therefore,

$$\frac{\mu'(x)}{\mu(x)} = -\frac{1}{x} \quad \Rightarrow \quad \ln(\mu) = -\ln(x) = \ln\left(\frac{1}{x}\right) \quad \Rightarrow \quad \mu(x) = \frac{1}{x}.$$

So the equation $\left(x^2e^y + \frac{1}{y}\right)y' + \left(2xe^y + \frac{1}{x}\right) = 0$ is exact. Indeed,

$$\begin{split} \tilde{N} &= \left(x^2 e^y + \frac{1}{y} \right) \quad \Rightarrow \quad \partial_x \tilde{N} = 2x e^y, \\ \tilde{M} &= \left(2x e^y + \frac{1}{x} \right) \quad \Rightarrow \quad \partial_y \tilde{M} = 2x e^y, \end{split} \qquad \Rightarrow \quad \partial_x \tilde{N} = \partial_y \tilde{M}. \end{split}$$

Example

Find every solution y of the equation

$$\left(x^2e^y+\frac{1}{y}\right)y'+\left(2x\,e^y+\frac{1}{x}\right)=0.$$

Solution: The equation is exact. We need to find the potential function ψ .

 $\partial_y \psi = N, \qquad \partial_x \psi = M.$

From the first equation we get:

$$\partial_y \psi = x^2 e^y + \frac{1}{y} \quad \Rightarrow \quad \psi = x^2 e^y + \ln(y) + g(x).$$

Introduce the expression for ψ in the equation $\partial_x \psi = M$, that is,

$$2xe^{y} + g'(x) = \partial_{x}\psi = M = 2xe^{y} + \frac{1}{x} \quad \Rightarrow \quad g'(x) = \frac{1}{x}$$

Review Exam 1.

Example

Find every solution y of the equation

$$\left(x^2e^y+\frac{1}{y}\right)y'+\left(2x\,e^y+\frac{1}{x}\right)=0.$$

Solution: Recall: $g'(x) = \frac{1}{x}$. Therefore $g(x) = \ln(x)$.

The potential function is $\psi = x^2 e^y + \ln(y) + \ln(x)$.

The solution y satisfies $x^2 e^{y(x)} + \ln(y(x)) + \ln(x) = c$.

 \triangleleft

Verification: Compute the implicit derivative in the equation above, and you should get the original differential equation.

$$2xe^{y} + x^{2}e^{y}y' + \frac{1}{y}y' + \frac{1}{x} = 0.$$

Example

Find every solution of the initial value problem

$$y' = 4x(y + \sqrt{y}), \qquad y(0) = 4.$$

Solution: The equation is: Not linear. It is a Bernoulli equation: $y' - 4x y = 4x y^n$, with n = 1/2. It is separable: $\frac{y'}{y + \sqrt{y}} = 4x$.

The equation is not homogeneous. It is not exact.

Although the equation is both separable and Bernoulli, it is not simple to integrate using the separable equation method. Indeed

$$\int \frac{y'}{y + \sqrt{y}} \, dt = \int 4x \, dx + c \quad \Rightarrow \quad \int \frac{dy}{y + \sqrt{y}} = 2x^2 + c.$$

The integral on the left-hand side requires an integration table.

Review Exam 1.

Example

Find every solution of the initial value problem

$$y' = 4x(y + \sqrt{y}), \qquad y(0) = 4.$$

Solution: We find solutions using the Bernoulli method.

$$y' - 4x y = 4x y^{1/2} \quad \Rightarrow \quad \frac{y'}{y^{1/2}} - 4x y^{1/2} = 4x.$$

Change the unknowns: $v = 1/y^{n-1}$, with n = 1/2. That is,

$$v = rac{1}{y^{-1/2}} \quad \Rightarrow \quad v = y^{1/2}, \quad \Rightarrow \quad v' = rac{1}{2} \, rac{y'}{y^{1/2}}$$

 $2v'-4xv=4x \quad \Rightarrow \quad v'-2xv=2x.$

The coefficient function is a(x) = -2x, so $A(x) = -x^2$, and the integrating factor is $\mu(x) = e^{-x^2}$.

Example

Find every solution of the initial value problem

$$y' = 4x(y + \sqrt{y}), \qquad y(0) = 4.$$

Solution: Recall: v' - 2xv = 2x and $\mu(x) = e^{-x^2}$.

$$e^{-x^2}v' - 2xe^{-x^2}v = 2x e^{-x^2} \stackrel{\text{Verify!}}{\Longrightarrow} (e^{-x^2}v)' = 2xe^{-x^2}.$$

 $e^{-x^2}v = \int 2xe^{-x^2} dx + c \quad \Rightarrow \quad e^{-x^2}v = -e^{-x^2} + c.$

We conclude that $v = c e^{x^2} - 1$. The initial condition for y implies the initial condition for v, that is, $v(x) = \sqrt{y(x)}$ implies v(0) = 2.

$$2 = v(0) = c - 1 \quad \Rightarrow \quad c = 3 \quad \Rightarrow \quad v(x) = 3e^{x^2} - 1.$$

finally find $y = v^2$, that is, $y(x) = (3e^{x^2} - 1)^2$.

Review Exam 1.

Example

We

Find the domain of the function y solution of the IVP

$$y'=-\frac{2t}{y}, \qquad y(1)=2.$$

Solution: We first need to find the solution y. The equation is separable.

$$y y' = -2t \quad \Rightarrow \quad \int y y' dt = \int -2t dt + c \quad \Rightarrow \quad \frac{y^2}{2} = -t^2 + c$$
$$\frac{4}{2} = \frac{y^2(1)}{2} = -1 + c \quad \Rightarrow \quad c = 3 \quad \Rightarrow \quad y(t) = \sqrt{2(3 - t^2)}.$$

The domain of the solution y is $D = (-\sqrt{3}, \sqrt{3})$.

The points $\pm\sqrt{3}$ do not belong to the domain of y, since y' and the differential equation are not defined there.

Example

Find the domain of the function y solution of the IVP

$$y' = -\frac{2t}{y}, \qquad y(t_0) = y_0 > 0.$$

Solution: The solution y is given as above, $\frac{y^2}{2} = -t^2 + c$. The initial condition implies

$$\frac{y_0^2}{2} = \frac{y^2(t_0)}{2} = -t_0^2 + c \implies c = \frac{y_0^2}{2} + t_0^2 \implies \frac{y^2}{2} = -t^2 + t_0^2 + \frac{y_0^2}{2}$$

The solution to the IVP is $y(t) = \sqrt{2(t_0^2 - t^2) + y_0^2}$.

The domain of the solution depends on the initial condition t_0 , y_0 :

$$D = \left(-\sqrt{t_0^2 + \frac{y_0^2}{2}}, +\sqrt{t_0^2 + \frac{y_0^2}{2}}\right).$$

Review Exam 1.

Example

Find every solution y to the equation $y' = -\frac{2x + 3y}{3x + 4y}$.

Solution: The equation is not linear, not Bernoulli, not separable. It is homogeneous. (Multiply numerator and denominator on the right hand side by (1/x).) Is it exact? (3x + 4y)y' + (2x + 3y) = 0 implies $\partial_x N = 3 = \partial_y M$. So the equation is exact.

We choose here the exact equation method. (Finding the potential function is sometimes simpler that solving homogeneous Eqs.)

We need to find the potential function $\psi {:}$

 $\partial_y \psi = N \quad \Rightarrow \quad \psi = 3xy + 2y^2 + g(x).$

$$\partial_x \psi = M \quad \Rightarrow \quad 3y + g'(x) = 2x + 3y \quad \Rightarrow \quad g(x) = x^2.$$

We conclude: $\psi(x, y) = 3xy + 2y^2 + x^2$, and $\psi(x, y(x)) = c$.

Example

Find every solution y to the equation $y' = -\frac{2x + 3y}{3x + 4y}$.

Solution: If we solve the problem using that the equation is homogeneous, it is more complicated than the previous calculation. We just start the calculation to see the difficulty:

$$y' = -\frac{(2x+3y)}{(3x+4y)}\frac{\left(\frac{1}{x}\right)}{\left(\frac{1}{x}\right)} = -\frac{2+3\left(\frac{y}{x}\right)}{3+4\left(\frac{y}{x}\right)}$$

The change v = y/x implies y = xv and y' = v + xv'. Hence

$$v + x v' = \frac{2 + 3v}{3 + 4v} \quad \Rightarrow \quad x v' = \frac{2 + 3v}{3 + 4v} - v = \frac{2 + 3v - 3v + 4v^2}{3 + 4v}$$

We conclude that v satisfies $\frac{3+4v}{2-4v^2}v' = \frac{1}{x}$.

Review Exam 1.

Example

Find every solution y to the equation $y' = -\frac{2x + 3y}{3x + 4y}$.

Solution: Recall: $\frac{3+4v}{2-4v^2}v'=\frac{1}{x}$.

This equation is complicated to integrate.

$$\int \frac{3v'}{2-4v^2}\,dx + \int \frac{4v\,v'}{2-4v^2}\,dx = \int \frac{1}{x}\,dx + c = \ln(x) + c.$$

The usual substitution u = v(x) implies du = v' dx, so

$$\int \frac{3\,du}{2-4u^2} + \int \frac{4u\,du}{2-4u^2} = \ln(x) + c.$$

The first integral on the left-hand side requires integration tables.

This is why the exact method is simpler to use in this case. \lhd
