# Hyperplane Arrangements

A (real) hyperplane arrangement is a (finite) collection of  $(n-1)$ -dimensional affine subspaces of  $\mathbb{R}^n$ .

---

# Faces of Hyperplane Arrangements

Each hyperplane partitions  $\mathbb{R}^n$  into three subsets!

The hyperplane itself

and

Two half spaces

# Faces of Hyperplane Arrangements

Each hyperplane partitions  $\mathbb{R}^n$  into three subsets!

The hyperplane itself

and

Two half spaces

---

The *faces* of an arrangement are obtained by picking one such subset for *each* hyperplane, then taking the intersection.

# Faces of Hyperplane Arrangements

The above arrangement has 25 faces

- 9 two-dimensional faces (chambers)
- 12 one-dimensional faces
- 4 zero-dimensional faces

# The Braid Arrangement

The Braid Arrangement  $\mathcal{A}_{n-1}$  is the collection of hyperplanes

$$\{x_i = x_j \mid 1 \leq i < j \leq n\} \subseteq \mathbb{R}^n$$

# Faces of the Braid Arrangement

The faces of  $\mathcal{A}_{n-1}$  are indexed by ordered set partitions of  $\{1, 2, \dots, n\}$

---

Let  $\mathcal{F}_n$  denote the set of faces of  $\mathcal{A}_{n-1}$ .

# The Action of $S_n$ on $\mathbb{F}_n$

The symmetric group  $S_n$  acts on  $\mathbb{F}_n$  by permuting coordinates.

There are  $2^{n-1}$   $S_n$ -orbits, indexed by integer compositions of  $n$ :  $\alpha \models n$ .

## $\mathbb{C} \mathcal{F}_n$ as an $S_n$ -representation

The vector space  $\mathbb{C} \mathcal{F}_n := \text{span}_{\mathbb{C}} \{ F \in \mathcal{F}_{n-1} \}$  is an  $S_n$ -representation.

### Recall

- For a finite group  $G$ , a representation of  $G$  consists of a:
  - $\mathbb{C}$ -vector space  $V$
  - Linear action  $G \curvearrowright V$
- We "understand" a  $G$ -representation by decomposing it into a direct sum of irreducible  $G$ -representations.

Irreducible representations of  $S_n$  are indexed by partitions  $\lambda \vdash n$ !

$\chi^\lambda$

# Writing $S_n$ -representations as Symmetric Functions

Let  $\bigoplus_{n \geq 0} \text{Char}_n$  denote the ring of characters of  $S_n$

---

There is an inner-product preserving ring isomorphism:

$ch: \bigoplus_{n \geq 0} \text{Char}_n \longrightarrow \bigwedge$  ring of symmetric functions

$\uparrow_{S_n} \longmapsto h_n$  "complete homogeneous symmetric function"

$\chi^\lambda \longmapsto s_\lambda$  "Schur function"

# $\mathbb{C} \mathfrak{F}_n$ as an $S_n$ -representation

For  $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_k)$ , let  $h_\alpha := h_{\alpha_1} \cdot h_{\alpha_2} \cdot \dots \cdot h_{\alpha_k}$ .

$$\text{ch}(\mathbb{C} \mathfrak{F}_n) = \sum_{\alpha \models n} h_\alpha = \sum_{\alpha \models n} K_{\lambda, \alpha} s_\lambda.$$

Kostka numbers

## Example

$$\text{ch}(\mathbb{C} \mathfrak{F}_3) = h_3 + h_{21} + h_{12} + h_{111}$$

# Outline

I. Faces of hyperplane arrangements

II. The Face Algebra + its history

III. Connections to Solomon's descent algebra

IV. Invariant theory for the face algebra

# Face Multiplication

- The faces of a hyperplane arrangement form a noncommutative semigroup.
- If the arrangement is central, the faces form a monoid.

# The Face Algebra

The vector space  $\mathbb{C} \mathfrak{F}_n$  is actually an algebra called the **face algebra**.

The face algebra is studied ...

①  In the context of Markov Chains / Card Shuffling 

Bidigare, Brown, Diaconis, Denham, Hankin, Lafrenière, Reiner, Rockmore, Saliola, Uemura-Reyes, Welker, and more

② As an algebra with combinatorial representation theory:

Aguilar-Mahajan, Bastidas, Bidigare, Saliola, Schöcker, and more

③ For its connections to Solomon's descent algebra

Aguilar-Mahajan, Saliola, Schöcker, and more

# The face algebra + shuffling

Let  $y = \frac{1}{3}(x_1 > x_2 = x_3) + \frac{1}{3}(x_3 > x_1 = x_2) + \frac{1}{3}(x_2 > x_3 = x_1).$

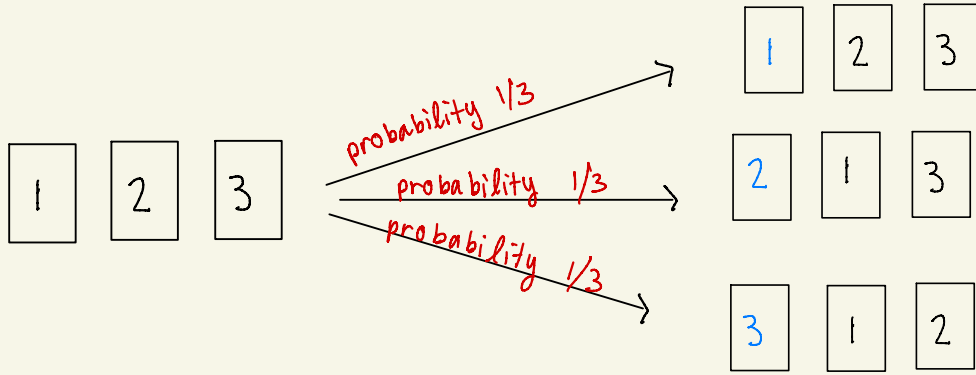

Then,

$$y \cdot (x_1 > x_2 > x_3) = \frac{1}{3}(x_1 > x_2 > x_3) + \frac{1}{3}(x_3 > x_1 > x_2) + \frac{1}{3}(x_2 > x_1 > x_3).$$

# Random-to-top shuffling

$$y \cdot (x_1 > x_2 > x_3)$$

||

$$\frac{1}{3} (x_1 > x_2 > x_3) + \frac{1}{3} (x_2 > x_1 > x_3) + \frac{1}{3} (x_3 > x_1 > x_2)$$

# Random Walks + Shuffling in the Face Algebra

The subspace of **chambers** (which can be thought of as the subspace of decks of cards on  $\{1, 2, \dots, n\}$ ) is **closed under multiplication** by  $\mathbb{C}\mathfrak{F}_n$ .

Bidigare - Hanlon - Rockmore '99:

- Several popular Markov chains can be modeled within  $\mathbb{C}\mathfrak{F}_n$  by

(some elt  
of  $\mathbb{C}\mathfrak{F}_n$ )  $\curvearrowright$  (Chamber subspace).

- Developed **uniform** formulas involving the combinatorics of the arrangement to compute the **eigenvalues** of such Markov chains  
of probabilistic interest for bounding mixing time

## Example: Eigenvalues of Random-to-top Shuffling

Random-to-top as a matrix:  
on  $\mathbb{C}S_n$

$$\begin{array}{l} 123 \\ 132 \\ 213 \\ 231 \\ 312 \\ 321 \end{array} \begin{pmatrix} 1/3 & 0 & 1/3 & 1/3 & 0 & 0 \\ 0 & 1/3 & 0 & 0 & 1/3 & 1/3 \\ 1/3 & 1/3 & 1/3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1/3 & 1/3 & 1/3 \\ 1/3 & 1/3 & 0 & 0 & 1/3 & 0 \\ 0 & 0 & 1/3 & 1/3 & 0 & 1/3 \end{pmatrix} \quad n=3$$

Theorem (Phatarfod '91, proof simplified by Bidigare-Hanlon-Rockmore approach)

- After scaling by  $n$ , the eigenvalues of random-to-top on  $\mathbb{C}S_n$  are  $0, 1, 2, \dots, n-2, n$ .
- The multiplicity of the eigenvalue  $i$  is  $\# \{ \pi \in S_n : \pi \text{ has exactly } i \text{ fixed points} \}$ .

# Riffle Shuffling

# Outline

I. Faces of hyperplane arrangements

II. The Face Algebra + its history

III. Connections to Solomon's descent algebra

IV. Invariant theory for the face algebra

# Solomon's descent algebra

- The descent set  $\text{Des}(\sigma)$  of a permutation  $\sigma \in S_n$  consists of the positions  $1 \leq i \leq n-1$  for which  $\sigma(i) > \sigma(i+1)$ .

$$\hookrightarrow \text{Des}(\underline{7} \underline{5} \underline{1} \underline{3} \underline{2} \underline{6} + 89) = \{1, 2, 4, 6\}$$

↖ one-line notation

- For  $J \subseteq \{1, 2, \dots, n-1\}$ , define

$$x_J := \sum_{\substack{\sigma \in S_n \\ \text{Des}(\sigma) = J}} \sigma \in \mathbb{C} S_n,$$

- The  $2^{n-1}$ -dim vector space  $\text{span}_{\mathbb{C}} \{x_J \mid J = \{1, 2, \dots, n-1\}\}$  is closed under multiplication, so forms a subalgebra of  $\mathbb{C} S_n$  called

Solomon's descent algebra:  $\Sigma_n$ .

# The $S_n$ -invariant subalgebra of $\mathbb{C}\tilde{\mathcal{F}}_n$

- The action of  $S_n$  on  $\mathbb{C}\tilde{\mathcal{F}}_n$  is by algebra automorphisms
- The  $S_n$ -invariant subalgebra  $(\mathbb{C}\tilde{\mathcal{F}}_n)^{S_n}$  consists of the elements fixed under the action of  $S_n$ .

Example  $(\mathbb{C}\tilde{\mathcal{F}}_4)^{S_4} =$

## The key connection

Thm (Bidigare): The descent algebra is anti-isomorphic to the  $S_n$ -invariant subalgebra of the face algebra:

$$\Sigma_n^{\text{opp}} \cong (\mathbb{C}\tilde{\mathcal{F}}_n)^{S_n}$$

↳ A useful way to view  $\Sigma_n$ : Saliola computed its quiver using this embedding

# Representation Theory of Finite Dimensional Algebras

- A representation of a finite dimensional algebra consists of a
- $\mathbb{C}$ -vector space  $V$ , and a
  - linear action\*  $A \curvearrowright V$
- 

Example:

The face algebra is a (right) representation of the descent algebra.

$$\mathbb{C}\mathfrak{F}_n \curvearrowright \Sigma_n \quad \text{via} \quad y \circ x := \underline{\Phi}^{-1}(x) \cdot y$$

Bidigane anti-isomorphism

---

Unlike group representations over  $\mathbb{C}$ , algebra representations do not always decompose into a **direct sum** of irreducible representations.

↳ i.e.  $A$  is **not** semisimple

How do we "understand" representations of nonsemisimple algebras?

One Option: **filtrations** of an  $A$ -representation  $V$  by subrepresentations,

$$0 \subsetneq V_1 \subsetneq V_2 \subsetneq \dots \subsetneq V_k = V \quad \text{with each } V_i/V_{i-1} \text{ irreducible.}$$

Up to isomorphism, the multiset of irreducibles  $\{V_i/V_{i-1}\}$  is **independent** of the filtration!

**Composition Multiplicity** of  $M$  in  $V$  =  $[V:M]$  = # of times  $M$  (up to isomorphism) appears in  $\{V_i/V_{i-1}\}$ .

# (Right) Representation Theory of $\Sigma_n$

- Studied in depth by Garsia-Reutenauer, generalized to other types by E. Bergeron, N. Bergeron, Howlett, Taylor

- $\Sigma_n$  is not semisimple

- Integer partitions of  $n$

Irreducible representations

Idempotents

in a complete family of primitive, orthogonal idempotents

one-dimensional!

- To understand a  $\Sigma_n$ -rep'n  $V$ :

↳ Count the composition multiplicity  $[V : M_\lambda]$  for each  $\lambda$

# Outline

I. Faces of hyperplane arrangements

II. The Face Algebra + its history

III. Connections to Solomon's descent algebra

IV. Invariant theory for the face algebra

# The Face Algebra as a Simultaneous Representation

---

We've seen:

But also:

---

How about:

?

# Isotypic components: Generalizations of invariant subalgebras

Finite group  $G$  acting on a fin. dim.  $\mathbb{C}$ -algebra  $\mathbb{R}$  by algebra homomorphisms.

For an irreducible  $G$ -representation  $\chi$ :

$\mathbb{R}^\chi = \chi$ -isotypic component

= direct sum of all copies of  $\chi$  in any decomp of  $\mathbb{R}$

Invariant Subalgebra

$G$ -isotypic components

Each isotypic subspace  $\mathbb{R}^\chi$  is an  $\mathbb{R}^G$ -module.

# My Question

How does each  $S_n$ -isotypic component  $(\mathbb{C}\tilde{\mathcal{F}}_n)^{\chi^\nu}$  look as a representation of  $\Sigma_n$ ?

$(\mathbb{C}\tilde{\mathcal{F}}_n)^{\chi^\mu}$ ??	$\hookrightarrow \Sigma_n$
$\vdots$	
$(\mathbb{C}\tilde{\mathcal{F}}_n)^{\chi^\lambda}$ ??	$\hookrightarrow \Sigma_n$
$(\mathbb{C}\tilde{\mathcal{F}}_n)^{\chi^\nu}$ ??	$\hookrightarrow \Sigma_n$
$(\mathbb{C}\tilde{\mathcal{F}}_n)^{S_n} \cong \Sigma_n^{\text{opp}}$	$\hookrightarrow \Sigma_n$

## Motivation

- Standard question in classical invariant theory
- Natural Extension of Bieligare's work, who studied  $(\mathbb{C}\tilde{\mathcal{F}}_n)^{\chi^\nu}$  for  $\chi^\nu$ 
  - the **trivial** representation  $\chi^n$
  - the **sign** representation  $\chi^{1^n}$
- New examples of  $\Sigma_n$ -representations

# A first approximation

Proposition As  $\Sigma_n$ -representations

$$(\mathbb{C}\Sigma_n)^{\chi_\nu} = \bigoplus_{\mu \text{ dominates } \nu} (\mathbb{C}\tilde{\Sigma}_n E_\mu)^{\chi_\nu}, \quad \text{with}$$

$$\dim_{\mathbb{C}} (\mathbb{C}\tilde{\Sigma}_n E_\mu)^{\chi_\nu} = \# \left\{ \text{compositions } \alpha \mid \alpha \begin{array}{l} \text{rearranges} \\ \text{to } \mu \end{array} \right\} \cdot \# \text{SYT}(\nu) \cdot K_{\nu, \mu}$$

↑  
Standard Young tableaux

↑

# Garsia - Reutenauer's Cartan Invariants of $\Sigma_n$

- Every word has a unique factorization into lexicographically weakly decreasing Lyndon words

S<sub>n</sub> - irreducible subspaces

$\chi_{111}$					$M_{\square}$
$\chi_{21}$			$3M_{\square}$	$3M_{\square}$	$3M_{\square}$
$\chi_{32}$			$2M_{\square}$	$2M_{\square}$	$2M_{\square}$
$\chi_{31}$	$3M_{\square}$	$3M_{\square}$	$3M_{\square}$	$6M_{\square}$	$3M_{\square}$
$\chi_4$	$M_{\square}$	$M_{\square}$	$M_{\square}$	$M_{\square}$	$M_{\square}$
	$e_{2, E_4}$	$e_{2, E_3}$	$e_{2, E_2}$	$e_{2, E_1}$	$e_{2, E_{11}}$

Word $w$	Lyndon Factorization	Lyndon Type ( $w$ )
5614311236	$(\underbrace{56}_1) (\underbrace{143}_8) (\underbrace{11236}_{13})$	(13, 11, 8)
121123	(12) (1123)	(7, 3)

Thm (Garsia - Reutenauer, 1989)

$$\left[ \left( \mathbb{C} \Sigma_n \right)^{S_n} E_{\mu} : M_{\lambda} \right] = \# \left\{ \begin{array}{l} \text{compositions} \\ \text{rearranging to } \mu \end{array} \right\} \left. \vphantom{\left[ \left( \mathbb{C} \Sigma_n \right)^{S_n} E_{\mu} : M_{\lambda} \right]} \right| \text{Lyndon Type } (\alpha) = \lambda \left. \vphantom{\left[ \left( \mathbb{C} \Sigma_n \right)^{S_n} E_{\mu} : M_{\lambda} \right]} \right\}.$$

# The Full Table

How many  $M_\lambda$ 's to draw?  $x^\nu$

$\mathbb{C} E_\mu$

Thm; (C., 2024)

$$[(\mathbb{C} \mathbb{F}_n)^{x^\nu} E_\mu : M_\lambda] = \#\text{SYT}(\nu) \cdot \langle s_\nu, \text{coefficient of } \underline{x}_\lambda \underline{y}_\mu \text{ in } F \rangle,$$

where  $F = \prod_{\substack{\text{Lyndon} \\ \text{words} \\ w}} \sum_{\substack{\text{partitions} \\ \tau}} \frac{x_{\tau \cdot |w|}}{|w|} (y_w)^{|\tau|} \mathcal{L}_\tau [h_w].$

## Notation

- $\underline{x}_\lambda := x_{\lambda_1} x_{\lambda_2} \dots x_{\lambda_k}$
- $|\nu|, |w| :=$  sum of the parts of  $\nu$  and the letters of  $w$ .
- $\nu \cdot k :=$  scaling of the parts of  $\nu$  by  $k$

# Proof Ingredients

Understanding a  $\Sigma_n$ -representation

$$[(\mathbb{C}\Sigma_n)^{\chi_\nu} E_M : M_\lambda] ?$$

Understanding an  $S_n$ -representation

$$E_\lambda \subset \mathbb{C}\Sigma_n E_M ?$$

Poset Topology

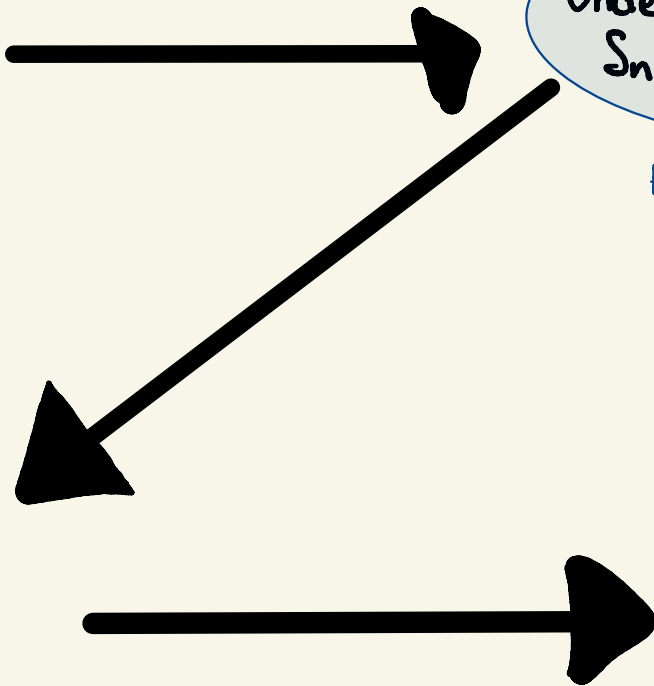

$$\bigoplus_{\substack{[X \leq Y] \\ X \in \mu \\ Y \in \lambda}} \tilde{H}_{top}(\Pi_n(X, Y)) \otimes \text{Det}(Y) \otimes \text{Det}(X) \xrightarrow{S_n} \text{Stab}_{S_n}(X) \cap \text{Stab}_{S_n}(Y) ?$$

homology of intervals in the lattice of set partitions

Symmetric Functions

$$\prod_w \sum_{\tau} \frac{x^{|\tau|} (y_w)^{|\tau|}}{w} \mathcal{L}_\tau[h_w]$$

Lyndon words  $w$  Partitions  $\tau$

Thank you!
