(b) For each critical point of \( f \), determine whether \( f \) has a local maximum, local minimum, or saddle point at that point.

Solution:

(a) \( \nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle = \langle 0, 0 \rangle \), then,

\[ x^2 = 2y, \quad y = 2x, \]
Example

(a) Find all the critical points of \( f(x, y) = 12xy - 2x^3 - 3y^2 \).
(b) For each critical point of \( f \), determine whether \( f \) has a local maximum, local minimum, or saddle point at that point.

Solution:
(a) \( \nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle = \langle 0, 0 \rangle \), then,

\( x = 4 \Rightarrow y = 8 \).
That is, there are two critical points, 
\( (0, 0) \) and 
\( (4, 8) \).
Example

(a) Find all the critical points of \( f(x, y) = 12xy - 2x^3 - 3y^2 \).

(a) \( \nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle = \langle 0, 0 \rangle \), then,

\[
    x^2 = 2y, \quad y = 2x, \quad \Rightarrow \quad x(x - 4) = 0.
\]

There are two solutions, \( x = 0 \Rightarrow y = 0 \), and \( x = 4 \Rightarrow y = 8 \).

There are two solutions, \( x = 0 \Rightarrow y = 0 \), and \( x = 4 \Rightarrow y = 8 \). That is, there are two critical points, \((0, 0)\) and \((4, 8)\).
Section 14.7

Example

(a) Find all the critical points of \( f(x, y) = 12xy - 2x^3 - 3y^2 \).

(b) For each critical point of \( f \), determine whether \( f \) has a local maximum, local minimum, or saddle point at that point.

Solution:
(b) Recalling \( \nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle \),
Section 14.7

Example

(a) Find all the critical points of $f(x, y) = 12xy - 2x^3 - 3y^2$.

(b) For each critical point of $f$, determine whether $f$ has a local maximum, local minimum, or saddle point at that point.

Solution:

(b) Recalling $\nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle$, we compute

\[
\begin{align*}
f_{xx} &= -12x, \\
f_{yy} &= -6, \\
f_{xy} &= 12.
\end{align*}
\]
Section 14.7

Example

(a) Find all the critical points of \( f(x, y) = 12xy - 2x^3 - 3y^2 \).

(b) For each critical point of \( f \), determine whether \( f \) has a local maximum, local minimum, or saddle point at that point.

Solution:

(b) Recalling \( \nabla f(x, y) = \langle 12y - 6x^2, 12x - 6y \rangle \), we compute

\[
\begin{align*}
f_{xx} &= -12x, & f_{xy} &= 12, & f_{yy} &= -6, \\
D(x, y) &= f_{xx}f_{yy} - (f_{xy})^2 = 144 \left( \frac{x}{2} - 1 \right),
\end{align*}
\]

Since \( D(0, 0) = -144 < 0 \), the point \((0, 0)\) is a saddle point of \( f \).

Since \( D(4, 8) = 144(2 - 1) > 0 \), and \( f_{xx}(4, 8) = (-12)4 < 0 \), the point \((4, 8)\) is a local maximum of \( f \).

\end{align*}
\]

\[
D(x, y) = f_{xx}f_{yy} - (f_{xy})^2 = 144 \left( \frac{x}{2} - 1 \right),
\]

Since \( D(0, 0) = -144 < 0 \), the point \((0, 0)\) is a saddle point of \( f \).

Solution:
We start finding the critical points inside the triangular region.

\[ \nabla f(x, y) = \left< y - 2, x - \frac{1}{2}y \right> \]
Example

Solution:
We start finding the critical points inside the triangular region.

\[
\nabla f(x, y) = \langle y - 2, x - \frac{1}{2}y \rangle = \langle 0, 0 \rangle,
\]

Solution:
We start finding the critical points inside the triangular region.

$$\nabla f(x, y) = \left< y - 2, x - \frac{1}{2}y \right> = \left< 0, 0 \right>, \quad \Rightarrow \quad y = 2, \quad y = 2x.$$
Section 14.7

Solution:
We start finding the critical points inside the triangular region.

\[
\nabla f(x, y) = \left\langle y - 2, x - \frac{1}{2}y \right\rangle = \langle 0, 0 \rangle, \quad \Rightarrow \quad y = 2, \quad y = 2x.

Solution:
We start finding the critical points inside the triangular region.

$$\nabla f(x, y) = \left< y - 2, x - \frac{1}{2}y \right> = \left< 0, 0 \right>, \quad \Rightarrow \quad y = 2, \quad y = 2x.$$ 

The solution is (1, 2). This point is outside in the triangular region given by the problem, so there is no critical point inside the region.

in the closed triangular region with vertices given by (0, 0), (1, 0), and (0, 2).

Solution:

1. The horizontal side of the triangle, \( y = 0 \), \( x \in (0, 1) \). Since

\[ g(x) = f(x, 0) = 2 - 2x, \]

2. The vertical side of the triangle is \( x = 0 \), \( y \in (0, 2) \). Then,

\[ g(y) = f(0, y) = 2 - \frac{1}{4}y^2, \]

\[ g'(y) = -\frac{1}{2}y = 0, \]
so \( y = 0 \) and we recover the point (0, 0).

Solution:

- The horizontal side of the triangle, \( y = 0, \ x \in (0, 1) \). Since

Solution:

► The horizontal side of the triangle, $y = 0$, $x \in (0, 1)$. Since

$$g(x) = f(x, 0) = 2 - 2x, \quad \Rightarrow \quad g'(x) = -2 \neq 0.$$  

there are no candidates in this part of the boundary.

► The vertical side of the triangle is $x = 0$, $y \in (0, 2)$. Then,

vertices given by \((0, 0), (1, 0), \) and \((0, 2)\).

Solution:

- The horizontal side of the triangle, \( y = 0, x \in (0, 1) \). Since

\[
g(x) = f(x, 0) = 2 - 2x, \quad \Rightarrow \quad g'(x) = -2 \neq 0.
\]

there are no candidates in this part of the boundary.

- The vertical side of the triangle is \( x = 0, y \in (0, 2) \). Then,

Solution:

- The horizontal side of the triangle, \( y = 0, \ x \in (0, 1) \). Since

  \[ g(x) = f(x, 0) = 2 - 2x, \quad \Rightarrow \quad g'(x) = -2 \neq 0. \]

  there are no candidates in this part of the boundary.

- The vertical side of the triangle is \( x = 0, \ y \in (0, 2) \). Then,

  \[ g(y) = f(0, y) = 2 - \frac{1}{4}y^2, \quad \Rightarrow \quad g'(y) = -\frac{1}{2}y = 0, \]

  so \( y = 0 \) and we recover the point \((0, 0)\).
Example

Solution:

- The hypotenuse of the triangle \( y = 2 - 2x, \ x \in (0, 1) \).
Example

Find the absolute maximum and absolute minimum of \( f(x, y) = 2 + xy - 2x - \frac{1}{4}y^2 \) in the closed triangular region with vertices given by \((0, 0), (1, 0), \) and \((0, 2)\).

Solution:

▷ The hypotenuse of the triangle \( y = 2 - 2x, \ x \in (0, 1) \). Then,

\[
g(x) = f(x, 2 - 2x) = 2 + x(2 - 2x) - 2x - \frac{1}{4}(2 - 2x)^2, \\
= 2 + 2x - 2x^2 - 2x - (x^2 - 2x + 1), \\
= 1 + 2x - 3x^2.
\]
Example

Solution:

1. The hypotenuse of the triangle \( y = 2 - 2x, \ x \in (0, 1) \). Then,

\[
g(x) = f(x, 2 - 2x) = 2 + x(2 - 2x) - 2x - \frac{1}{4}(2 - 2x)^2,
\]

\[
= 2 + 2x - 2x^2 - 2x - (x^2 - 2x + 1),
\]

\[
= 1 + 2x - 3x^2.
\]

Then, \( g'(x) = 2 - 6x = 0 \) implies \( x = \frac{1}{3} \).
Section 14.7

Example
Find the absolute maximum and absolute minimum of \( f(x, y) = 2 + xy - 2x - \frac{1}{4}y^2 \) in the closed triangular region with vertices given by \((0, 0), (1, 0), \) and \((0, 2)\).

Solution:

- The hypotenuse of the triangle \( y = 2 - 2x, \ x \in (0, 1) \). Then,

\[
g(x) = f(x, 2 - 2x) = 2 + x(2 - 2x) - 2x - \frac{1}{4}(2 - 2x)^2,
\]

\[
= 2 + 2x - 2x^2 - 2x - \left(x^2 - 2x + 1\right),
\]

\[
= 1 + 2x - 3x^2.
\]

Then, \( g'(x) = 2 - 6x = 0 \) implies \( x = \frac{1}{3} \), hence \( y = \frac{4}{3} \).
Example

Find the absolute maximum and absolute minimum of \( f(x, y) = 2 + xy - 2x - \frac{1}{4}y^2 \) in the closed triangular region with vertices given by (0, 0), (1, 0), and (0, 2).

Solution:

- The hypotenuse of the triangle \( y = 2 - 2x, \ x \in (0, 1) \). Then,

\[
g(x) = f(x, 2 - 2x) = 2 + x(2 - 2x) - 2x - \frac{1}{4}(2 - 2x)^2,
\]

\[
= 2 + 2x - 2x^2 - 2x - (x^2 - 2x + 1),
\]

\[
= 1 + 2x - 3x^2.
\]

Then, \( g'(x) = 2 - 6x = 0 \) implies \( x = \frac{1}{3} \), hence \( y = \frac{4}{3} \). The candidate is \( \left( \frac{1}{3}, \frac{4}{3} \right) \).

Solution:

- Recall that we have obtained a candidate point $(\frac{1}{3}, \frac{4}{3})$. We evaluate $f$ at this point,

$$f\left(\frac{1}{3}, \frac{4}{3}\right) = 2 + \frac{4}{9} - \frac{2}{3} - \frac{116}{49} = \frac{4}{3}.$$

Solution:
▷ Recall that we have obtained a candidate point \((\frac{1}{3}, \frac{4}{3})\). We evaluate \(f\) at this point,
\[

\]
Recalling that \(f(0, 0) = 2, f(1, 0) = 0, \) and \(f(0, 2) = 1, \) the absolute maximum is at \((0, 0)\), and the minimum is at \((1, 0)\). \(\triangle\)

(b) Use the approximation above to estimate the value of $f(-2.8, 2.3)$.

Solution:

(a) $L(x, y) = f_x(-3, 2)(x + 3) + f_y(-3, 2)(y - 2) + f(-3, 2)$.

Since $f_x(x, y) = 2\cos(2x + 3y)$ and $f_y(x, y) = 3\cos(2x + 3y)$,

$$f_x(-3, 2) = 2\cos(-6 + 6) = 2,$$
$$f_y(-3, 2) = 3\cos(-6 + 6) = 3,$$
$$f(-3, 2) = \sin(-6 + 6) + 1 = 1.$$

The linear approximation is $L(x, y) = 2(x + 3) + 3(y - 2) + 1$. 
Example

(b) Use the approximation above to estimate the value of \( f(-2.8, 2.3) \).

Solution:

(b) Recall: \( L(x, y) = 2(x + 3) + 3(y - 2) + 1 \).

(b) Use the approximation above to estimate the value of $f(-2.8, 2.3)$.

Solution:
(b) Recall: $L(x, y) = 2(x + 3) + 3(y - 2) + 1$. Now, the linear approximation of $f(-2.8, 2.3)$ is $L(-2.8, 2.3)$, and

$$L(-2.8, 2.3) = 2(-2.8 + 3) + 3(2.3 - 2) + 2$$

$$= 2(0.2) + 3(0.3) + 1$$

$$= 2.3.$$

Example

(a) Find the linear approximation $L(x, y)$ of the function $f(x, y) = \sin(2x + 3y) + 1$ at the point $(-3, 2)$.

(b) Use the approximation above to estimate the value of $f(-2.8, 2.3)$.

Solution:

(b) Recall: $L(x, y) = 2(x + 3) + 3(y - 2) + 1$.

Now, the linear approximation of $f(-2.8, 2.3)$ is $L(-2.8, 2.3)$, and

\[
L(-2.8, 2.3) = 2(-2.8 + 3) + 3(2.3 - 2) + 2 \\
= 2(0.2) + 3(0.3) + 1 \\
= 2.3.
\]

We conclude $L(-2.8, 2.3) = 2.3$. □

Example

Use Fubini’s Theorem to compute the double integral
\[ \int \int_{R} f(x, y) \, dx \, dy, \]
where \( f(x, y) = xy^2 + 2x^2y^3 \), and \( R = [0, 2] \times [1, 3] \). Integrate first in \( x \), then in \( y \).

Solution: Since \( x \in [0, 2] \) and \( y \in [1, 3] \),

\[
\int \int_R f(x, y) \, dx \, dy = \int_1^3 \int_0^2 (xy^2 + 2x^2y^3) \, dx \, dy

Solution: The boundary is the ellipse $\frac{x^2}{9} + \frac{y^2}{4} = 1$.
So, the boundary as Type I is given by

$$y = -2\sqrt{1 - \frac{x^2}{9}} = g_1(x), \quad y = 2\sqrt{1 - \frac{x^2}{9}} = g_2(x).$$

The boundary as Type II is given by

$$x = -3\sqrt{1 - \frac{y^2}{4}} = h_1(y).$$
Domains Type I and Type II.

Example

Find the limits of integration of \( \int \int_D f(x, y) \, dx \, dy \) in the domain \( D = \{(x, y) \in \mathbb{R}^2 : \frac{x^2}{9} + \frac{y^2}{4} \leq 1\} \) when \( D \) is considered first as Type I and then as Type II.

Solution: The boundary is the ellipse \( \frac{x^2}{9} + \frac{y^2}{4} = 1 \). So, the boundary as Type I is given by

\[
y = -2\sqrt{1 - \frac{x^2}{9}} = g_1(x), \quad y = 2\sqrt{1 - \frac{x^2}{9}} = g_2(x).
\]

The boundary as Type II is given by

\[
x = -3\sqrt{1 - \frac{y^2}{4}} = h_1(y), \quad x = 3\sqrt{1 - \frac{y^2}{4}}
\]
Domains Type I and Type II.

Example

Reverse the order of integration in $\int_0^1 \int_1^{e^x} dy \, dx$.
Domains Type I and Type II.

Example

Reverse the order of integration in \( \int_{0}^{1} \int_{1}^{e^x} dy \, dx \).

Solution:

This integral is written as Type I, since we first integrate on vertical intervals \([1, e^x]\), with boundaries \(y = e^x, \, y = 1\), while \(x \in [0, 1]\).
Domains Type I and Type II.

Example
Reverse the order of integration in $\int_{0}^{1} \int_{e^{-x}}^{1} dy \, dx$.

Solution:
This integral is written as Type I, since we first integrate on vertical intervals $[1, e^x]$, with boundaries $y = e^x$, $y = 1$, while $x \in [0, 1]$.

By inverting the first equation and looking at the figure we get the left and right boundaries:

$$x = \ln(y), \quad x = 1, \quad \text{with} \quad y \in [1, e].$$
Domains Type I and Type II.

Example

Reverse the order of integration in $\int_0^1 \int_1^{e^x} dy \, dx$.

Solution:

This integral is written as Type I, since we first integrate on vertical intervals $[1, e^x]$, with boundaries $y = e^x$, $y = 1$, while $x \in [0, 1]$.

By inverting the first equation and looking at the figure we get the left and right boundaries:

$$x = \ln(y), \quad x = 1, \quad \text{with} \quad y \in [1, e].$$

Therefore, we conclude that $\int_0^1 \int_1^{e^x} dy \, dx = \int_1^e \int_{\ln(y)}^1 dx \, dy$. \triangle
