Theorem

Given continuous functions p, $q:(t_1,t_2) \to \mathbb{R}$, let $y_1:(t_1,t_2) \to \mathbb{R}$ be a solution of

y'' + p(t)y' + q(t)y = 0,

If the function $v : (t_1, t_2) \rightarrow \mathbb{R}$ is solution of

$$y_{I}(t) v'' + [2y'(t) + p(t)y_{I}(t)] v' = 0.$$
 (1)

then the functions y_1 and $y_2 = v y_1$ are fundamental solutions to the differential equation above.

then the functions y_1 and $y_2 = v y_1$ are fundamental solutions to the differential equation above.

Remark: The reason for the name Reduction of order method is that the function v does not appear in Eq. (1). This is a first order equation in v'.

Let P be a primitive of p, that is, P'(t) = p(t),
Proof: Recall $y_1 v'' + (2y'_1 + p y_1) v' = 0$. We now need to show that y_1 and $y_2 = vy_1$ are linearly independent.

$$W_{y_1y_2} = egin{bmatrix} y_1 & vy_1 \ y_1' & (v'y_1 + vy_1') \end{bmatrix} = y_1(v'y_1 + vy_1') - vy_1y_1'.$$

We obtain $W_{y_1y_2} = v'y_1^2$. We need to find v'. Denote w = v', so

$$y_1 w' + (2y'_1 + p y_1) w = 0 \quad \Rightarrow \quad \frac{w'}{w} = -2\frac{y'_1}{y_1} - p.$$

Let P be a primitive of p, that is, P'(t) = p(t), then

$$\ln(w) = -2\ln(y_1) - P$$

Proof: Recall $y_1 v'' + (2y'_1 + p y_1) v' = 0$. We now need to show that y_1 and $y_2 = vy_1$ are linearly independent.

$$W_{y_1y_2} = egin{bmatrix} y_1 & vy_1 \ y_1' & (v'y_1 + vy_1') \end{bmatrix} = y_1(v'y_1 + vy_1') - vy_1y_1'.$$

We obtain $W_{y_1y_2} = v'y_1^2$. We need to find v'. Denote w = v', so

$$y_1 w' + (2y_1' + p y_1) w = 0 \quad \Rightarrow \quad \frac{w'}{w} = -2\frac{y_1'}{y_1} - p.$$

Let P be a primitive of p, that is, P'(t) = p(t), then

 $\ln(w) = -2\ln(y_1) - P \Rightarrow w = e^{[\ln(y_1^{-2}) - P]}$

Proof: Recall $y_1 v'' + (2y'_1 + p y_1) v' = 0$. We now need to show that y_1 and $y_2 = vy_1$ are linearly independent.

$$W_{y_1y_2} = egin{bmatrix} y_1 & vy_1 \ y_1' & (v'y_1 + vy_1') \end{bmatrix} = y_1(v'y_1 + vy_1') - vy_1y_1'.$$

We obtain $W_{y_1y_2} = v'y_1^2$. We need to find v'. Denote w = v', so

$$y_1 w' + (2y_1' + p y_1) w = 0 \quad \Rightarrow \quad \frac{w'}{w} = -2\frac{y_1'}{y_1} - p.$$

Let P be a primitive of p, that is, P'(t) = p(t), then

$$\ln(w) = -2\ln(y_1) - P \implies w = e^{[\ln(y_1^{-2}) - P]} \implies w = y_1^{-2} e^{-P}.$$

Proof: Recall $y_1 v'' + (2y'_1 + p y_1) v' = 0$. We now need to show that y_1 and $y_2 = vy_1$ are linearly independent.

$$W_{y_1y_2} = egin{bmatrix} y_1 & vy_1 \ y_1' & (v'y_1 + vy_1') \end{bmatrix} = y_1(v'y_1 + vy_1') - vy_1y_1'.$$

We obtain $W_{y_1y_2} = v'y_1^2$. We need to find v'. Denote w = v', so

$$y_1 w' + (2y_1' + p y_1) w = 0 \quad \Rightarrow \quad \frac{w'}{w} = -2\frac{y_1'}{y_1} - p.$$

Let P be a primitive of p, that is, P'(t) = p(t), then

$$\ln(w) = -2\ln(y_1) - P \Rightarrow w = e^{[\ln(y_1^{-2}) - P]} \Rightarrow w = y_1^{-2} e^{-P}.$$

We obtain $v'y_1^2 = e^{-P}$, hence $W_{y_1y_2} = e^{-P}$, which is non-zero.

Proof: Recall $y_1 v'' + (2y'_1 + p y_1) v' = 0$. We now need to show that y_1 and $y_2 = vy_1$ are linearly independent.

$$W_{y_1y_2} = \begin{vmatrix} y_1 & vy_1 \\ y_1' & (v'y_1 + vy_1') \end{vmatrix} = y_1(v'y_1 + vy_1') - vy_1y_1'.$$

We obtain $W_{y_1y_2} = v'y_1^2$. We need to find v'. Denote w = v', so

$$y_1 w' + (2y_1' + p y_1) w = 0 \quad \Rightarrow \quad \frac{w'}{w} = -2\frac{y_1'}{y_1} - p.$$

Let P be a primitive of p, that is, P'(t) = p(t), then

$$\ln(w) = -2\ln(y_1) - P \Rightarrow w = e^{[\ln(y_1^{-2}) - P]} \Rightarrow w = y_1^{-2} e^{-P}.$$

We obtain $v'y_1^2 = e^{-P}$, hence $W_{y_1y_2} = e^{-P}$, which is non-zero. We conclude that y_1 and $y_2 = vy_1$ are linearly independent.

Solution: Recall: $y_p(t) = k e^{2t}$. We need to find k.

(4) Trivial here, since $L(y_p) \neq 0$, we do not modify our guess. (Recall: $L(y_h) = 0$ iff $y_h(t) = c_1 e^{4t} + c_2 e^{-t}$.)

Example

Solution: We know that the general solution to homogeneous equation is $y_h(t) = c_1 e^{4t} + c_2 e^{-t}$.

Following the table we guess y_p as $y_p = k e^{4t}$.

However, this guess satisfies $L(y_p) = 0$.

So we modify the guess to $y_p = kt e^{4t}$.

Example

Solution: We know that the general solution to homogeneous equation is $y_h(t) = c_1 e^{4t} + c_2 e^{-t}$.

Following the table we guess y_p as $y_p = k e^{4t}$.

However, this guess satisfies $L(y_p) = 0$.

So we modify the guess to $y_p = kt e^{4t}$.

Introduce the guess into $L(y_p) = f$.

Example

However, this guess satisfies $L(y_p) = 0$.

So we modify the guess to $y_p = kt e^{4t}$.

Introduce the guess into $L(y_p) = f$. We need to compute

$$y'_{p} = k e^{4t} + 4kt e^{4t}, \qquad y''_{p} = 8k e^{4t} + 16kt e^{4t}.$$

Example

Find all the solutions to the inhomogeneous equation

$$y'' - 3y' - 4y = 3e^{2t} + 2\sin(t).$$

Solution: We know that the general solution y is given by

$$y(t) = y_h(t) + y_{p_1}(t) + y_{p_2}(t),$$

where $y_h(t) = c_1 e^{4t} + c_2 e^{2t}$, $L(y_{p_1}) = 3e^{2t}$, and $L(y_{p_2}) = 2\sin(t)$. We have just found out that

$$y_{p}(t) = -\frac{1}{2}e^{2t}, \qquad y_{p_{2}}(t) = \frac{1}{17}\left[-5\sin(t) + 3\cos(t)\right].$$

We conclude that

$$y(t) = c_1 e^{4t} + c_2 e^{2t} - \frac{1}{2} e^{2t} + \frac{1}{17} \left[-5\sin(t) + 3\cos(t) \right].$$

The variation of parameter method can be applied to more general equations than the undetermined coefficients method.

Remarks:

 This is a general method to find solutions to equations having variable coefficients and non-homogeneous with a continuous but otherwise arbitrary source function,

$$y'' + p(t) y' + q(t) y = f(t).$$

- The variation of parameter method can be applied to more general equations than the undetermined coefficients method.
- The variation of parameter method usually takes more time to implement than the simpler method of undetermined coefficients.

Theorem (Variation of parameters)

Let $p, q, f: (t_1, t_2) \to \mathbb{R}$ be continuous functions, let y_1 , $y_2: (t_1, t_2) \to \mathbb{R}$ be linearly independent solutions to the homogeneous equation

y'' + p(t) y' + q(t) y = 0,

and let $W_{y_1y_2}$ be the Wronskian of y_1 and y_2 . If the functions u_1 and u_2 are defined by

$$u_1(t) = \int -\frac{y_2(t)f(t)}{W_{y_1y_2}(t)} dt, \qquad u_2(t) = \int \frac{y_1(t)f(t)}{W_{y_1y_2}(t)} dt,$$

then the function $y_p = u_1y_1 + u_2y_2$ is a particular solution to the non-homogeneous equation

$$y'' + p(t) y' + q(t) y = f(t).$$

We know that $y_1 = t^2$ and $y_2 = 1/t$.

Example

Find a particular solution to the differential equation

$$t^2y'' - 2y = 3t^2 - 1,$$

knowing that the functions $y_1 = t^2$ and $y_2 = 1/t$ are solutions to the homogeneous equation $t^2y'' - 2y = 0$.

Solution: First, write the equation in the form of the Theorem. That is, divide the whole equation by t^2 ,

$$y'' - \frac{2}{t^2}y = 3 - \frac{1}{t^2} \quad \Rightarrow \quad f(t) = 3 - \frac{1}{t^2}.$$

We know that $y_1 = t^2$ and $y_2 = 1/t$. Their Wronskian is

$$W_{y_1y_2}(t) = (t^2) \left(\frac{-1}{t^2}\right) - (2t) \left(\frac{1}{t}\right)$$

Example

Find a particular solution to the differential equation

$$t^2y'' - 2y = 3t^2 - 1,$$

knowing that the functions $y_1 = t^2$ and $y_2 = 1/t$ are solutions to the homogeneous equation $t^2y'' - 2y = 0$.

Solution: First, write the equation in the form of the Theorem. That is, divide the whole equation by t^2 ,

$$y'' - \frac{2}{t^2}y = 3 - \frac{1}{t^2} \quad \Rightarrow \quad f(t) = 3 - \frac{1}{t^2}.$$

We know that $y_1 = t^2$ and $y_2 = 1/t$. Their Wronskian is

$$W_{y_1y_2}(t) = (t^2) \Big(\frac{-1}{t^2} \Big) - (2t) \Big(\frac{1}{t} \Big) \quad \Rightarrow \quad W_{y_1y_2}(t) = -3.$$

Example

Find a particular solution to the differential equation

$$t^2y'' - 2y = 3t^2 - 1,$$

knowing that the functions $y_1 = t^2$ and $y_2 = 1/t$ are solutions to the homogeneous equation $t^2y'' - 2y = 0$.

Solution: If we do not remember the formulas for u_1 , u_2 , we can always solve the system

$$\begin{aligned} u_1'y_1 + u_2'y_2 &= 0\\ u_1'y_1' + u_2'y_2' &= f. \end{aligned}$$

$$t^2 u_1' + u_2'\frac{1}{t} = 0, \quad 2t u_1' + u_2'\frac{(-1)}{t^2} = 3 - \frac{1}{t^2}. \end{aligned}$$
