

Products by substitution. In this section, we develop methods to find indefinite integrals (antiderivatives) of products of trig functions, beyond the direct antiderivatives:

$$\int \cos(x) dx = \sin(x), \quad \int \sin(x) dx = -\cos(x), \quad \int \sec^2(x) dx = \tan(x),$$

$$\int \tan(x) \sec(x) dx = \sec(x), \quad \int \csc^2(x) dx = -\cot(x), \quad \int \cot(x) \csc(x) dx = -\csc(x).$$

The easiest cases allow a simple trig substitution reducing to a polynomial, often using $\sin^2 + \cos^2 = 1$ or $\tan^2 + 1 = \sec^2$. Let m, n be integers with $n \geq 0$.

- (a) $\int \sin^m(x) \cos^{2n+1}(x) dx$: take $u = \sin(x)$, $du = \cos(x) dx$.
 $\int \cos^m(x) \sin^{2n+1}(x) dx$: take $u = \cos(x)$, $du = -\sin(x) dx$.

$$\begin{aligned} \int \sin^{-10}(x) \cos^3(x) dx &= \int \sin^{-10}(x) \cos^2(x) \cdot \cos(x) dx \\ &= \int \sin^{-10}(x) (1 - \sin^2(x)) \cdot \cos(x) dx \\ &= \int u^{-10} (1 - u^2) du \\ &= \int u^{-10} - u^{-8} du \\ &= \frac{1}{-9} u^{-9} - \frac{1}{-7} u^{-7} + C \\ &= -\frac{1}{9} \sin^{-9}(x) + \frac{1}{7} \sin^{-7}(x) + C. \end{aligned}$$

$$\begin{aligned} \int \sin^5(x) dx &= -\int \sin^4(x) \cdot (-\sin(x)) dx \\ &= -\int (1 - \cos^2(x))^2 \cdot (-\sin(x)) dx \\ &= -\int (1 - u^2)^2 du \\ &= -\int (1 - 2u^2 + u^4) du \\ &= -u + \frac{2}{3} u^3 - \frac{1}{5} u^5 + C \\ &= -\cos(x) + \frac{2}{3} \cos^3(x) - \frac{1}{5} \cos^5(x) + C. \end{aligned}$$

- (b) $\int \tan^m(x) \sec^{2n+2}(x) dx$: take $u = \tan(x)$, $du = \sec^2(x) dx$.

$$\begin{aligned} \int \tan^{-3}(x) \sec^6(x) dx &= \int \tan^{-3}(x) \sec^4(x) \cdot \sec^2(x) dx \\ &= \int \tan^{-3}(x) (\tan^2(x) + 1)^2 \cdot \sec^2(x) du \\ &= \int u^{-3} (u^2 + 1)^2 du \\ &= \int (u + 2u^{-1} + u^{-3}) du \\ &= \frac{1}{2} u^2 + \ln|u| - \frac{1}{2} u^{-2} + C \\ &= \frac{1}{2} \tan^2(x) + \ln|\tan(x)| - \frac{1}{2} \cot^2(x) + C. \end{aligned}$$

For brevity, we will henceforth omit the constant of integration $+C$.

Remaining cases. What if a product of trig functions does not fit types (a) or (b)?

- Rewrite in terms of sin and cos, obtaining $\sin^p(x) \cos^q(x)$ for integers p, q . Use type (a) if p is odd and positive, or if q is odd and positive. Reduce to type (b) if p and q are both even with $p+q$ negative; or if p and q are both odd and negative.

$$\begin{aligned} \int \sin^2(x) \cos(x) \tan^2(x) \csc(x) dx &= \int \sin^2(x) \cos(x) \frac{\sin^2(x)}{\cos^2(x)} \frac{1}{\sin(x)} dx \\ &= \int (\cos(x))^{-1} \sin^3(x) dx = -\ln |\cos(x)| + \frac{1}{2} \cos^2(x), \text{ type (a).} \end{aligned}$$

$$\begin{aligned} \int \csc^2(x) dx &= \int \frac{1}{\sin^2(x)} dx = \int \frac{\cos^2(x)}{\sin^2(x) \cos^2(x)} dx = \int \tan^{-2}(x) \sec^2(x) dx \\ &= \int u^{-2} du = -u^{-1} = -(\tan(x))^{-1} = -\cot(x), \text{ type (b).} \end{aligned}$$

$$\begin{aligned} \int \frac{1}{\sin^3(x) \cos(x)} dx &= \int \frac{\cos^3(x)}{\sin^3(x) \cos^4(x)} dx = \int \tan^{-3}(x) \sec^4(x) dx \\ &= \int (u^2 + 1)u^{-3} du = \ln |\tan(x)| - \frac{1}{2} \cot^2(x), \text{ type (b).} \end{aligned}$$

- Pythagorean identities: $\int \tan^4(x) dx = \int (\sec^2(x) - 1) \tan^2(x) dx$
 $= \int \sec^2(x) \tan^2(x) dx - \int (\sec^2(x) - 1) dx = \frac{1}{3} \tan^3(x) - \tan(x) + x$, type (b).
- For even positive powers of sin and cos, rewrite using the identities: $\sin^2(x) = \frac{1}{2}(1 - \cos(2x))$, $\cos^2(x) = \frac{1}{2}(1 + \cos(2x))$, $\sin(x) \cos(x) = \frac{1}{2} \sin(2x)$.

$$\begin{aligned} \int \sin^6(x) dx &= \int \left(\frac{1}{2}(1 - \cos(2x))\right)^3 dx \\ &= \frac{1}{8} \int 1 - 3 \cos(2x) + 3 \cos^2(2x) - \cos^3(2x) dx \\ &= \frac{1}{8} \int 1 - 3 \cos(2x) + \frac{3}{2}(1 + \cos(4x)) - \cos^3(2x) dx, \end{aligned}$$

where we used the binomial formula $(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$. Now each term can be done directly, or by type (a) with the substitution $u = \sin(2x)$.

Recalcitrant cases. In case of odd negative powers of sin or cos, we need special tricks.

EXAMPLE: The integral of secant $\int \sec(x) dx$ was needed by map-makers in the 1600's, when Calculus was first developed. It calibrates stretching in the Mercator projection, which makes map directions match compass directions. An amazing trick from §6.2:

$$\begin{aligned} \int \sec(x) dx &= \int \sec(x) \frac{\sec(x) + \tan(x)}{\sec(x) + \tan(x)} dx \\ &= \int \frac{1}{\sec(x) + \tan(x)} \cdot (\sec^2(x) + \sec(x) \tan(x)) dx = \int \frac{1}{u} du \end{aligned}$$

for $u = \sec(x) + \tan(x)$, $du = (\sec(x) \tan(x) + \sec^2(x)) dx$.

Thus:

$$\int \sec(x) dx = \ln|u| = \ln|\sec(x) + \tan(x)|.$$

Another trick for this is to write $\int \sec(x) dx = \int \frac{1}{\cos^2(x)} \cos(x) dx$, and substitute $u = \sin(x)$ to get $\int \frac{1}{1-u^2} du$. We will see how to integrate such rational functions in §7.4.

EXAMPLE: Here is a tricky integration by parts, in which we get back to the same integral we started with:

$$\begin{aligned} \int \sec^3(x) dx &= \int \sec(x)(1 + \tan^2(x)) dx = \int \sec(x) dx + \underbrace{\int \tan(x)}_u \underbrace{\sec(x) \tan(x) dx}_{dv} \\ &= \ln|\sec(x) + \tan(x)| + \underbrace{\tan(x)}_u \underbrace{\sec(x)}_v - \underbrace{\int \sec(x)}_v \underbrace{\sec^2(x) dx}_{du} \end{aligned}$$

Since we have $\int \sec^3(x) dx$ on both sides *with opposite signs*, we can solve for it to get:

$$\int \sec^3(x) dx = \frac{1}{2} \left(\ln|\sec(x) + \tan(x)| + \tan(x) \sec(x) \right).$$

Trig integrals with inside coefficients. Add together the angle addition identities:

$$\cos(a+b) = \cos(a)\cos(b) - \sin(a)\sin(b)$$

$$\cos(a-b) = \cos(a)\cos(b) + \sin(a)\sin(b)$$

$$\frac{1}{2}(\cos(a+b) + \cos(a-b)) = \cos(a)\cos(b).$$

This allows us to do integrals of the form:

$$\begin{aligned} \int \cos(nx) \cos(mx) dx &= \int \frac{1}{2} \cos(nx+mx) + \frac{1}{2} \cos(nx-mx) dx \\ &= \frac{1}{2(n+m)} \sin((n+m)x) + \frac{1}{2(n-m)} \sin((n-m)x) + C. \end{aligned}$$

Similarly:

$$\frac{1}{2}(\cos(a-b) - \cos(a+b)) = \sin(a)\sin(b)$$

$$\frac{1}{2}(\sin(a+b) + \sin(a-b)) = \sin(a)\cos(b).$$

Tangent half-angle substitution. For a really messy trigonometric integral like:

$$\int \frac{\cos^2(x) \sin(x) - 2 \tan(x) + 1}{\sec^3(x) + \sin^3(x) + 3 \cos(x) \sin(x) + 5} dx,$$

there is a general method in the extra notes, the Geometric Trig Substitution:

$$\sin(x) = \frac{2t}{1+t^2}, \quad \cos(x) = \frac{1-t^2}{1+t^2}, \quad dx = \frac{2}{1+t^2} dt, \quad t = \tan\left(\frac{1}{2}x\right) = \frac{\sin(x)}{1+\cos(x)}.$$

This reduces the trig integral to the integral of a rational function, which can be done by Partial Fractions (§7.4).
