Lecture Notes on Random Variables and Stochastic Processes

This lecture notes mainly follows Chapter 1-7 of the book Foundations of Modern Probability by Olav Kallenberg. We will omit some parts.

1 Elements of Measure Theory

We begin with elementary notation of set theory. We use union $A \cup B$ or $\bigcup_{\alpha} A_{\alpha}$, intersection $A \cap B$ or $\bigcap_{\alpha} A_{\alpha}$, difference $A \setminus B = \{x \in A : x \notin B\}$, and symmetric difference $A \triangle B = (A \setminus B) \cup (B \setminus A)$. A partition of a set $A$ is a family $A_{t} \subset A$, $t \in T$, such that $A = \bigcup_{t} A_{t}$, and for any $t_1 \neq t_2$, $A_{t_1} \cap A_{t_2} = \emptyset$. If a whole space $\Omega$ is fixed and contains all relative sets, the complement $A^c$ is $\Omega \setminus A$. Recall that

$$A \cap \left(\bigcup_{\alpha} B_{\alpha}\right) = \bigcup_{\alpha} (A \cap B_{\alpha}), \quad A \cup \left(\bigcap_{\alpha} B_{\alpha}\right) = \bigcap_{\alpha} (A \cup B_{\alpha})$$

$$\left(\bigcup_{\alpha} A_{\alpha}\right)^c = \bigcap_{\alpha} A_{\alpha}^c, \quad \left(\bigcap_{\alpha} A_{\alpha}\right)^c = \bigcup_{\alpha} A_{\alpha}^c.$$

A $\sigma$-algebra or $\sigma$-field in a nonempty set $\Omega$ is defined as a collection of $\mathcal{A}$ of subsets of $\Omega$ such that

1. $\emptyset, \Omega \in \mathcal{A}$,
2. $A \in \mathcal{A}$ implies that $A^c \in \mathcal{A}$,
3. $A_n \in \mathcal{A}$ for all $n \in \mathbb{N}$ implies that $\bigcup_n A_n \in \mathcal{A}$ and $\bigcap_n A_n \in \mathcal{A}$.

We may also say that a $\sigma$-algebra is a class of subsets, which contains the empty set and the whole space, and is closed under complement, countable union and countable intersection. There are two trivial examples of $\sigma$-algebras. First, $\{\emptyset, \Omega\}$ is the smallest $\sigma$-algebra. Second, the collection $2^{\Omega}$ of all subsets of $\Omega$ is the biggest $\sigma$-algebra.

A measurable space is a pair $(\Omega, \mathcal{A})$, where $\Omega$ is a nonempty set and $\mathcal{A}$ is a $\sigma$-algebra in $\Omega$. Every element of $\mathcal{A}$ is called a measurable set.

We observe that if $\mathcal{A}_{\alpha}$, $\alpha \in A$, is a family of $\sigma$-algebras in $\Omega$, then $\bigcap_{\alpha} \mathcal{A}_{\alpha}$ is a $\sigma$-algebra in $\Omega$. We use this fact to define the $\sigma$-algebra generated by a collection of sets. Let $\mathcal{C} \subset 2^{\Omega}$, i.e.,
\( \mathcal{C} \) is a collection of subsets of \( \Omega \). Let \( \mathcal{M}(\mathcal{C}) \) be the set of all \( \sigma \)-algebra \( \mathcal{A} \) in \( \Omega \) such that \( \mathcal{C} \subset \mathcal{A} \).

We define

\[
\sigma(\mathcal{C}) = \bigcap_{\mathcal{A} \in \mathcal{M}(\mathcal{C})} \mathcal{A}.
\]

Then

1. \( \sigma(\mathcal{C}) \supset \mathcal{C} \) as \( \mathcal{A} \supset \mathcal{C} \) for every \( \mathcal{A} \in \mathcal{M}(\mathcal{C}) \).
2. \( \sigma(\mathcal{C}) \) is a \( \sigma \)-algebra in \( \Omega \) as it is the intersection of a collection of \( \sigma \)-algebras in \( \Omega \).

These two properties imply that \( \sigma(\mathcal{C}) \in \mathcal{M}(\mathcal{C}) \), and so is the smallest \( \sigma \)-algebra in \( \Omega \) that contains \( \mathcal{C} \). We call \( \sigma(\mathcal{C}) \) the \( \sigma \)-algebra generated by \( \mathcal{C} \).

There are no simple expressions of \( \sigma(\mathcal{C}) \) in terms of union, intersection, and complement of elements of \( \mathcal{C} \).

If \( S \) is a topological space, then the Borel \( \sigma \)-algebra \( \mathcal{B}(S) \) on \( S \) is the \( \sigma \)-algebra generated by the topology of \( S \), i.e., the collection of open subsets of \( S \). Thus, a topological space is also viewed as a measurable space. We write \( \mathcal{B} \) for \( \mathcal{B}(\mathbb{R}) \).

Besides \( \sigma \)-algebras, the following notation will be useful for us.

1. A \( \pi \)-system \( \mathcal{C} \) in \( \Omega \) is a class of subsets of \( \Omega \), which is closed under finite intersection, i.e., \( A, B \in \mathcal{C} \) implies that \( A \cap B \in \mathcal{C} \).
2. A \( \lambda \)-system \( \mathcal{D} \) in \( \Omega \) is a class of subsets of \( \Omega \), which contains \( \Omega \), and is closed under proper difference and increasing limits. The former means that \( A, B \in \mathcal{D} \) and \( A \supset B \) implies that \( A \setminus B \in \mathcal{D} \). The latter means that if \( A_1 \subset A_2 \subset A_2 \subset \cdots \in \mathcal{D} \), then \( \bigcup_n A_n \in \mathcal{D} \).

It is clear that \( \mathcal{A} \) is a \( \sigma \)-algebra if and only if it is both a \( \pi \)-system and a \( \lambda \)-system. If \( E \subset 2^\Omega \), we may similarly define the \( \pi \)-system \( \pi(E) \) and the \( \lambda \)-system \( \lambda(E) \) generated by \( E \), respectively.

The following monotone class theorem is very useful. An application of this result is called a monotone class argument.

**Theorem 1.1.** If \( \mathcal{C} \) is a \( \pi \)-system, then \( \sigma(\mathcal{C}) = \lambda(\mathcal{C}) \).

**Proof.** Since a \( \sigma \)-algebra containing \( \mathcal{C} \) is also a \( \lambda \)-system containing \( \mathcal{C} \), we have \( \lambda(\mathcal{C}) \subset \sigma(\mathcal{C}) \). We need to show that \( \sigma(\mathcal{C}) \subset \lambda(\mathcal{C}) \). It suffices to show that \( \lambda(\mathcal{C}) \) is a \( \sigma \)-algebra. Since it is already a \( \lambda \)-system, we only need to show that it is a \( \pi \)-system. This means we need to show that, if \( A, B \in \lambda(\mathcal{C}) \), then \( A \cap B \in \lambda(\mathcal{C}) \).

At the beginning, since \( \mathcal{C} \) is a \( \pi \)-system, we know that if \( A, B \in \mathcal{C} \), then \( A \cap B \in \mathcal{C} \subset \lambda(\mathcal{C}) \). Now we show that

\[
A \in \mathcal{C} \text{ and } B \in \lambda(\mathcal{C}) \text{ implies that } A \cap B \in \lambda(\mathcal{C}). \tag{1.1}
\]

We prove this statement in an indirect way. Fix \( A \in \mathcal{C} \). Consider the set

\[
\mathcal{S}_A := \{ B \subset \Omega : A \cap B \in \lambda(\mathcal{C}) \}.
\]

Then
Lemma 1.2. A space is called separable if it contains a countable dense set.

A natural question to ask is whether the Borel $\sigma$-algebra $\mathcal{A}$ of a measurable space $\Omega$ is about measurable spaces. For example, since $\mathbb{R}$ is about measurable spaces, we use the symbols $(\mathbb{R},\mathcal{B}^n)$ as the product of the Borel $\sigma$-algebras $(\mathbb{R},\mathcal{B}^n)$ and $(\mathbb{R},\mathcal{B}^n)$.

We remark that the product on the left is about topological spaces, and the product on the right is about measurable spaces. For example, since $\mathbb{R}$ is a separable metric space, $\mathcal{B}(\mathbb{R}^n) = \mathcal{B}^n$.

To check the second claim, we note that

1. $\Omega \in \mathcal{S}_A$ because $\Omega \cap A = A$;
2. If $B_1 \supset B_2 \in \mathcal{S}_A$, then $B_1 \cap A \supset B_2 \cap A$, and so $(B_1 \setminus B_2) \setminus A = (B_1 \cap A) \setminus (B_2 \cap A) \in \Lambda(C)$. Thus, $B_1 \setminus B_2 \in \mathcal{S}_A$;
3. If $B_1 \subset B_2 \subset B_3 \subset \cdots \in \mathcal{S}_A$, then $B_1 \cap A \subset B_2 \cap A \subset B_3 \cap A \subset \cdots \in \Lambda(C)$. So $\bigcup B_n \cap A = \bigcup (B_n \cap A) \in \Lambda(C)$, which implies that $\bigcup B_n \in \mathcal{S}_A$.

This means that $\mathcal{S}_A$ is a $\lambda$-system that contains $C$. So $\mathcal{S}_A$ contains $\lambda(C)$. This finishes the proof of (1.1).

Next we show that

$$A \in \lambda(C) \text{ and } B \in \lambda(C) \text{ implies that } A \cap B \in \lambda(C).$$

This is enough to conclude that $\lambda(C)$ is a $\pi$-system. For the proof, for any $A \in \lambda(C)$, we define $\mathcal{S}_A$ by the same way as before. By (1.1), $\mathcal{S}_A$ contains $C$. The argument in the last paragraph shows that $\mathcal{S}_A$ is a $\lambda$-system. So $\mathcal{S}_A$ contains $\lambda(C)$, and the proof is complete. $\square$

For any family of spaces $\Omega_t$, $t \in T$, the Cartesian product $\prod_t \Omega_t$ is the class of all collections $(\omega_t : t \in T)$, where $\omega_t \in \Omega_t$ for all $t \in T$. When $T = \{1, \ldots, n\}$ or $T = \mathbb{N} = \{1, 2, \ldots\}$, we write the product space as $\Omega_1 \times \cdots \times \Omega_n$ and $\Omega_1 \times \Omega_2 \times \cdots$. If all $\Omega_t = \Omega$, we use the notation $\Omega^T$, $\Omega^n$, or $\Omega^\infty$.

If each $\Omega_t$ is equipped with a $\sigma$-algebra $\mathcal{A}_t$, then we introduce the product $\sigma$-algebra $\prod_t \mathcal{A}_t$ as the $\sigma$-algebra in $\prod_t \Omega_t$ generated by the class of cylinder sets

$$\{A_t \times \prod_{s \neq t} \Omega_s = \{(\omega_s : s \in T) : \omega_t \in A_t \text{ and } \omega_s \in \Omega_s \text{ for } s \neq t \} : t \in T, A \in \mathcal{A}_t\}.$$ (1.2)

We call $(\prod_t \Omega_t, \prod_t \mathcal{A}_t)$ the product of the measurable spaces $(\Omega_t, \mathcal{A}_t)$, $t \in T$. In special cases, we use the symbols $\mathcal{A}_1 \times \cdots \times \mathcal{A}_n$, $\mathcal{A}_1 \times \mathcal{A}_2 \times \cdots$, $\mathcal{A}^T$, $\mathcal{A}^n$, $\mathcal{A}^\infty$.

In Topology, one may define product of topological space, which is also a topological space. A natural question to ask is whether the Borel $\sigma$-algebra generated by the product topology agrees with the product of the Borel $\sigma$-algebra generated by each topology. The answer is Yes if we only consider a countable product and each space is a separable metric space. A topological space is called separable if it contains a countable dense set.

**Lemma 1.2.** Let $S_1, S_2, \ldots$ be separable metric spaces. Then

$$\mathcal{B}(S_1 \times S_2 \times \cdots) = \mathcal{B}(S_1) \times \mathcal{B}(S_2) \times \cdots.$$ We remark that the product on the left is about topological spaces, and the product on the right is about measurable spaces. For example, since $\mathbb{R}$ is a separable metric space, $\mathcal{B}(\mathbb{R}^n) = \mathcal{B}^n$. 

For a class $C \subset \text{injective}$. Then we have $A$ for $\sigma$-algebra.

Proof. Let $\mathcal{T}_n$ denote the topology in $S_n$. Then $\sigma(\mathcal{T}_n) = \mathcal{B}(S_n)$. Let

$$C^n_\sigma = \{ A_n \times \prod_{m \neq n} S_m : A_n \in \mathcal{B}(S_n) \}, \quad C^n_T = \{ A_n \times \prod_{m \neq n} S_m : A_n \in \mathcal{T}_n \}, \quad n \in \mathbb{N};$$

$C_\sigma = \bigcup_n C^n_\sigma$ and $C_T = \bigcup_n C^n_T$. By definition of product $\sigma$-algebra,

$$\mathcal{B}(S_1) \times \mathcal{B}(S_2) \times \cdots = \sigma(C_\sigma).$$

On the other hand, the product topology on $S_1 \times S_2 \times \cdots$ is the topology generated by $C_T$. We denote it by $\mathcal{T}(C_T)$. Thus, the Borel $\sigma$-algebra on the product space is

$$\mathcal{B}(S_1 \times S_2 \times \cdots) = \sigma(\mathcal{T}(C_T)).$$

It remains to show that $\sigma(C_\sigma) = \sigma(\mathcal{T}(C_T))$. It is easy to show that $C^n_\sigma = \sigma(C^n_T)$ for each $n$. So

$$\sigma(C_\sigma) = \sigma(\bigcup_n C^n_\sigma) \subset \sigma(\bigcup_n \sigma(C^n_T)) = \sigma(\bigcup_n C^n_T) = \sigma(C_T) \subset \sigma(\mathcal{T}(C_T)).$$

For the other direction, we use the fact that each $\mathcal{T}_n$ has a countable base, i.e., there is a countable set $\mathcal{T}'_n \subset \mathcal{T}_n$ such that each element of $\mathcal{T}_n$ can be expressed as a union of some elements of $\mathcal{T}'_n$. To construct $\mathcal{T}'_n$, let $A_n$ be a countable dense subset of $S_n$ (because $S_n$ is separable), and let $\mathcal{T}'_n = \{ \{ w \in S_n : \text{dist}(w, z) < q \} : z \in A_n, q \in \mathbb{Q}_+ \}$. It is easy to check that $\mathcal{T}'_n$ satisfies the desired property. We may use $\mathcal{T}'_n$ to construct a countable basis of the topology in $S_1 \times S_2 \times \cdots$, namely

$$A_1 \times A_2 \times \cdots \times A_m \times S_{m+1} \times S_{m+1} \times \cdots,$$

where $m \in \mathbb{N}$ and $A_j \in \mathcal{T}'_j$ for $1 \leq j \leq m$. Every element of the countable basis belongs to $\sigma(C_\sigma)$. Since every open set in $S_1 \times S_2 \times \cdots$ is a countable union of elements in the basis, we have $\mathcal{T}(C_\sigma) \subset \sigma(C_\sigma)$. Thus, $\sigma(\mathcal{T}(C_T)) \subset \sigma(C_\sigma)$. The proof is then complete. 

Let $S$ and $T$ be two nonempty sets. A point mapping $f : S \to T$ induces two set mappings $f : 2^S \to 2^T$ and $f^{-1} : 2^T \to 2^S$ such that

$$fA = \{ f(x) : x \in A \}, \quad f^{-1}B = \{ x \in S : f(x) \in B \}$$

for $A \subset S$ and $B \subset T$. Note that for the definition of $f^{-1}$ we do not need $f$ to be surjective or injective. Then we have

$$f^{-1}B^c = (f^{-1}B)^c, \quad f^{-1} \bigcup_t B_t = \bigcup_t f^{-1}B_t, \quad f^{-1} \bigcap_t B_t = \bigcap_t f^{-1}B_t. \quad (1.3)$$

For a class $\mathcal{C} \subset 2^T$, we define

$$f^{-1}\mathcal{C} = \{ f^{-1}B : B \in \mathcal{C} \}.$$
Lemma 1.3. Let $\mathcal{S}$ and $\mathcal{T}$ be $\sigma$-algebras in $S$ and $T$, respectively. Then $f^{-1}\mathcal{T}$ is a $\sigma$-algebra in $S$ and $\{B \subseteq T : f^{-1}B \subseteq \mathcal{S}\}$ is a $\sigma$-algebra in $T$.

Proof. It follows directly from Lemma 1.3. \hfill \Box

In the setup of Lemma 1.3, we call $f^{-1}\mathcal{T}$, denoted by $\sigma(f)$, the $\sigma$-algebra induced or generated by $f$; and if $f^{-1}\mathcal{T} \subseteq \mathcal{S}$, then we say that $f$ is $\mathcal{S}/\mathcal{T}$-measurable or simply measurable if $\mathcal{S}$ and $\mathcal{T}$ are fixed. Note that $\sigma(f)$ is the smallest $\sigma$-algebra in $S$ w.r.t. which $f$ is measurable.

Lemma 1.4. If $\mathcal{C} \subseteq 2^T$ satisfies that $\mathcal{T} = \sigma(\mathcal{C})$, then $f^{-1}\mathcal{T} \subseteq \mathcal{S}$ if and only if $f^{-1}(\mathcal{C}) \subseteq \mathcal{S}$.

Proof. Clearly $f^{-1}\mathcal{T} \subseteq \mathcal{S}$ implies that $f^{-1}(\mathcal{C}) \subseteq \mathcal{S}$. On the other hand, if $f^{-1}(\mathcal{C}) \subseteq \mathcal{S}$ then by Lemma 1.3, the class of sets $B \subseteq T$ such that $f^{-1}(B) \subseteq \mathcal{S}$ is a $\sigma$-algebra in $T$. Such class contains $\mathcal{C}$ by assumption, and so it contains $\sigma(\mathcal{C}) = \mathcal{T}$. Thus, we get $f^{-1}\mathcal{T} \subseteq \mathcal{S}$. \hfill \Box

Lemma 1.5. If $f : S \to T$ is a continuous mapping between two topological spaces, then $f$ is measurable with respect to the Borel $\sigma$-algebras $\mathcal{B}(S)$ and $\mathcal{B}(T)$.

Proof. Let $\mathcal{T}_S$ and $\mathcal{T}_T$ be the topologies in $S$ and $T$, respectively. Then $\mathcal{B}(S) = \sigma(\mathcal{T}_S)$ and $\mathcal{B}(T) = \sigma(\mathcal{T}_T)$. By continuity of $f$, $f^{-1}\mathcal{T}_T \subseteq \mathcal{T}_S \subseteq \mathcal{B}(S)$. By Lemma 1.4, $f^{-1}\mathcal{B}(T) \subseteq \mathcal{B}(S)$. \hfill \Box

Let $\mathcal{C} \subseteq 2^S$ and $A \subseteq S$. We define

$$A \cap \mathcal{C} = \{A \cap B : B \in \mathcal{C}\} \subseteq 2^A.$$ 

It is clear that if $\mathcal{C}$ is a $\sigma$-algebra in $S$, then $A \cap \mathcal{C}$ is a $\sigma$-algebra in $A$. We then call $(A, A \cap \mathcal{C})$ a (measurable) subspace of $(S, \mathcal{C})$. This definition mimics that of topological subspaces.

Lemma 1.6 (slight variation). If $A \subseteq S$ and $\mathcal{C} \subseteq 2^S$, then $\sigma_A(A \cap \mathcal{C}) = A \cap \sigma_S(\mathcal{C})$. Here we use $\sigma_A(\cdot)$ (resp. $\sigma_S(\cdot)$) to denote the $\sigma$-algebra in $A$ (resp. $S$) generated by some class.

Proof. Since $\mathcal{C} \subseteq \sigma_S(\mathcal{C})$, $A \cap \mathcal{C} \subseteq A \cap \sigma_S(\mathcal{C})$. Since the RHS is a $\sigma$-algebra in $A$, we get $\sigma_A(A \cap \mathcal{C}) \subseteq A \cap \sigma_S(\mathcal{C})$. To prove the other direction, let $\overline{\mathcal{S}}$ denote the class of $B \subseteq S$ such that $A \cap B \in \sigma_A(A \cap \mathcal{C})$. Then $\overline{\mathcal{S}}$ contains $\mathcal{C}$ and $A \cap \overline{\mathcal{S}} \subseteq \sigma_A(A \cap \mathcal{C})$. Since $\sigma_A(A \cap \mathcal{C})$ is a $\sigma$-algebra in $A$, it is easy to see that $\overline{\mathcal{S}}$ is a $\sigma$-algebra in $S$. Thus, $\overline{\mathcal{S}} \supseteq \sigma_S(\mathcal{C})$, and so $A \cap \sigma_S(\mathcal{C}) \subseteq \sigma_A(A \cap \mathcal{C})$. \hfill \Box

Suppose $(S, \mathcal{C})$ is a topological space, and $A \subseteq S$. Then $A$ is a topological subspace with topology $A \cap \mathcal{C}$. By Lemma 1.6, $\mathcal{B}(A) = A \cap \mathcal{B}(S)$, and so $A$ is also a measurable subspace of $S$.

Lemma 1.7 (composition). For three measurable spaces $(S, \overline{\mathcal{S}})$, $(T, \overline{T})$, and $(U, \overline{U})$, and two measurable mappings $f : S \to T$ and $g : T \to U$, the composition $g \circ f : S \to U$ is measurable.

Proof. We have $(g \circ f)^{-1}\overline{U} = f^{-1}g^{-1}\overline{U} \subseteq f^{-1}\overline{T} \subseteq \overline{\mathcal{S}}$. \hfill \Box

Lemma 1.8. Let $(\Omega, \mathcal{A})$ and $(S_t, \overline{S_t})$, $t \in T$, be measurable spaces. Let $U \subseteq \prod_t S_t$ and $f : \Omega \to U$. Then $f$ is $U \cap \prod_t \overline{S_t}$-measurable if and only if for each $t \in T$, $f_t := \pi_t \circ f$ is $\overline{S_t}$-measurable, where $\pi_t : \prod_r S_r \to S_t$ is the $t$-th coordinate map.
Proof. Suppose \( f \) is \( U \cap \prod_t S_t \)-measurable. Fix \( t \in T \) and \( B \in \overline{S}_t \). We have

\[
f_t^{-1}B = f^{-1}(B \times \prod_{s \neq t} S_s) = f^{-1}(U \cap (B \times \prod_{s \neq t} S_s)) \in A.
\]

So \( f_t \) is \( \overline{S}_t \)-measurable. Now suppose each \( f_t \) is \( \overline{S}_t \)-measurable. Then for each cylinder set in \( S^T \) of the form \( B \times \prod_{s \neq t} S_s \), \( B \in \overline{S}_t \), we have \( f_t^{-1}(B \times \prod_{s \neq t} S_s) = f_t^{-1}B \in A \). Since the class of such cylinder sets generates the \( \sigma \)-algebra \( \prod_t \overline{S}_t \), by Lemma 1.4, \( f^{-1} \prod_t \overline{S}_t \subset A \). Thus, \( f \) is \( \prod_t \overline{S}_t \)-measurable if we treat it as a function from \( \Omega \) to \( \prod_t \overline{S}_t \). For any \( A \in U \cap \prod_t \overline{S}_t \), there is \( B \in \prod_t \overline{S}_t \) such that \( A = U \cap B \). Then \( f^{-1}A = f^{-1}B \in A \). So \( f \) is \( U \cap \prod_t \overline{S}_t \)-measurable. \( \square \)

Recall that \( \sigma(f) = f^{-1} \prod_t \overline{S}_t \) and \( \sigma(f_t) = f_t^{-1} \), \( t \in T \), are the \( \sigma \)-algebras in \( \Omega \) induced by \( f \) and \( f_t \), respectively. Let

\[
\sigma(f_t : t \in T) = \sigma(\bigcup_{t \in T} \sigma(f_t)),
\]

and we call it the \( \sigma \)-algebra generated by \( f_t, t \in T \).

Corollary. \( \sigma(f) = \sigma(f_t : t \in T) \).

Proof. This follows immediately from Lemma 1.8. We leave it as an exercise. \( \square \)

We use the following symbols:

\[
\mathbb{R}_+ = [0, \infty), \quad \mathbb{R} = (-\infty, \infty], \quad \mathbb{R}_+ = [0, \infty].
\]

The latter two spaces have Borel \( \sigma \)-algebras

\[
\mathcal{B}(\mathbb{R}) = \sigma(\mathcal{B}, \{\infty\}, \{-\infty\}), \quad \mathcal{B}(\mathbb{R}_+) = \sigma(\mathcal{B}(\mathbb{R}_+), \{\infty\}).
\]

We now fix a measurable space \((\Omega, \mathcal{A})\). A function \( f \) from \( \Omega \) into an interval \( I \subset \mathbb{R} \) is measurable if and only if for any \( x \in I \), \( \{\omega : f(\omega) \leq x\} \) is measurable. This follows from Lemma 1.4 and the fact that the class \((-\infty, x] \cap I, x \in I \), generates the \( \sigma \)-algebra \( \mathcal{B}(I) = I \cap \mathcal{B} \). We will often write \( \{f \leq x\} \) for \( \{\omega : f(\omega) \leq x\} \). The inequality \( x \) may be replaced by \( -\infty \) or \( \infty \), or \( x \). The statements also hold for \( I = \mathbb{R} \) or \( \mathbb{R}_+ \).

Lemma 1.9. For any sequence of measurable functions \( f_1, f_2, \ldots \) from \((\Omega, \mathcal{A})\) into \( \mathbb{R} \), \( \sup_n f_n \), \( \inf_n f_n \), \( \limsup_n f_n \) and \( \liminf_n f_n \) are also measurable.

Proof. We use the equalities

\[
\{\sup_n f_n \leq x\} = \bigcap_n \{f_n \leq x\}, \quad \{\inf_n f_n \geq x\} = \bigcap_n \{f_n \geq x\},
\]

\[
\limsup_n f_n = \inf_n \sup_{m \geq n} f_m, \quad \liminf_n f_n = \sup_n \inf_{m \geq n} f_m.
\]

\( \square \)
This lemma in particular implies that the limit of measurable functions (if it exists pointwise) is measurable. This statement also holds for a general metric space.

Lemma 1.10. Let \(f_1, f_2, \ldots\) be measurable functions from \((\Omega, \mathcal{A})\) into some metric space \((S, \rho)\). Then

(i) If \(f_n \to f\), then \(f\) is measurable.

(ii) If \((S, \rho)\) is separable and complete, then \(\{\omega : \lim f_n(\omega) \text{ converges}\}\) is measurable.

Proof. (i) If \(f_n \to f\), then for any continuous function \(g : S \to \mathbb{R}\), we have \(g \circ f_n \to g \circ f\). So \(g \circ f\) from \(\Omega\) to \(\mathbb{R}\) is measurable by Lemmas 1.5, 1.7 and 1.9. Fixing an open set \(G \subset S\). We may choose some continuous functions \(g_n : S \to \mathbb{R}_+\) such that \(g_n \uparrow 1_G\). In fact, we may let

\[g_n(s) = \min\{1, n\rho(s, G^c)\},\]

where \(\rho(s, G^c) = \inf\{\rho(s, t) : t \in G^c\}\) is the distance from \(s\) to \(G^c\), which is continuous in \(s\) by the triangle inequality. Since each \(g_n \circ f\) is measurable, \(1_G \circ f = 1_{f^{-1}G}\) is measurable. So \(f^{-1}(G)\) is measurable for every open set \(G\). By Lemma 1.4, \(f\) is measurable.

(ii) Since \(S\) is complete, \(\lim f_n(\omega)\) converges if and only if \((f_n(\omega))\) is a Cauchy sequence in \(S\). Now

\[\{\omega : (f_n(\omega)) \text{ is Cauchy in } S\} = \bigcap_{m} \bigcup_{N} \bigcap_{n_1 \geq N} \bigcap_{n_2 \geq N} \{\omega : \rho(f_{n_1}(\omega), f_{n_2}(\omega)) < \frac{1}{m}\}.\]

This formula is another way to state that \((f_n(\omega))\) is a Cauchy sequence if and only if for any \(m \in \mathbb{N}\) there exists \(N \in \mathbb{N}\) such that for any \(n_1, n_2 \geq N\), \(\rho(f_{n_1}(\omega), f_{n_2}(\omega)) < \frac{1}{m}\). To prove that the set on the RHS is measurable it suffices to show that for any \(m, n_1, n_2\), \(\{\omega : \rho(f_{n_1}(\omega), f_{n_2}(\omega)) < \frac{1}{m}\}\) is measurable. For that purpose, we use the fact that

(i) by Lemma 1.8, \((f_{n_1}, f_{n_2}) : \Omega \to S^2\) is \(\mathcal{A}/\mathcal{B}(S)^2\)-measurable;

(ii) the map \(S^2 \ni (s_1, s_2) \mapsto \rho(s_1, s_2) \in \mathbb{R}_+\) is continuous (follows easily from the triangle inequality), and so by Lemma 1.5 is measurable w.r.t. \(\mathcal{B}(S^2)\);

(iii) by Lemma 1.2, \(\mathcal{B}(S^2) = \mathcal{B}(S)^2\); (we use the separability of \(S\) here);

(iv) by Lemma 1.7, \(\rho(f_{n_1}, f_{n_2}) : \Omega \to \mathbb{R}_+\) is \(\mathcal{A}\)-measurable.

\[\square\]

Lemma 1.12. For any measurable function \(f, g : (\Omega, \mathcal{A}) \to \mathbb{R}\) and \(a, b \in \mathbb{R}\), \(af + bg\) and \(fg\) are measurable. If, in addition, \(g\) does not take value \(0\), then \(f/g\) is measurable.

Proof. To prove the measurability of \(af + bg\), we express \(af + bg\) as the composition of the map \((f, g) : \Omega \to \mathbb{R}^2\) and the continuous function \(\mathbb{R}^2 \ni (x, y) \mapsto ax + by \in \mathbb{R}\). The proof for \(fg\) is similar. For \(f/g\), we express \(f/g\) as the composition of \((f, g) : \Omega \to \mathbb{R} \times (\mathbb{R} \setminus \{0\})\) and the the continuous function \(\mathbb{R} \times (\mathbb{R} \setminus \{0\}) \ni (x, y) \mapsto x/y \in \mathbb{R}\).

\[\square\]
For any $A \subset \Omega$, we define the associated indicator function $1_A : \Omega \to \mathbb{R}$ to be equal to 1 on $A$ and to 0 on $A^c$. Sometimes we write $1_A$ instead of $1_A$. It is clear that $1_A$ is measurable (w.r.t. $A$) if and only if $A$ is a measurable set (w.r.t. $A$).

Linear combinations of indicator functions are called simple functions. Thus, a simple function $f : \Omega \to \mathbb{R}$ is of the form

$$f = c_11_{A_1} + \cdots + c_n1_{A_n},$$

where $n \in \mathbb{N}$, $A_1, \ldots, A_n \subset \Omega$ and $c_1, \ldots, c_n \in \mathbb{R}$. Here we only allow finite sums. If $A_1, \ldots, A_n \in \mathcal{A}$, then $f$ is $\mathcal{A}$-measurable, and called a measurable simple function.

**Lemma 1.11.** For any measurable function $f : (\Omega, \mathcal{A}) \to [0, \infty)$, there exist a sequence of measurable simple functions $f_n : (\Omega, \mathcal{A}) \to [0, \infty)$ such that $f_n \to f$.

We use the following symbols from now on. For $a, b \in \mathbb{R}$, we use $a \wedge b$ and $a \vee b$ to denote $\min\{a, b\}$ and $\max\{a, b\}$, respectively. The symbols also extend to $a_1 \wedge \cdots \wedge a_n$, $a_1 \vee \cdots \vee a_n$, $\land t a_t$, and $\lor t a_t$, where the latter two are alternative ways to write $\inf_t a_t$ and $\sup_t a_t$.

For $x \in \mathbb{R}$, we use $\lfloor x \rfloor$ to denote the biggest integer $n$ with $n \leq x$, and use $\lceil x \rceil$ to denote the smallest integer $n$ with $n \geq x$. Then $\lfloor x \rfloor$ and $\lceil x \rceil$ are monotone increasing.

**Proof.** We let

$$f_n = \frac{\lfloor 2^n (f \wedge n) \rfloor}{2^n}, \quad n \in \mathbb{N}.$$ 

Then $0 \leq f_n \leq f \wedge n$. We see that $f_n$ is a simple measurable function because it takes values in $\{\frac{k}{2^n} : 0 \leq k \leq n2^n\}$,

$$f_n^{-1}\left(\left\{\frac{k}{2^n}\right\}\right) = \{\omega : \frac{k}{2^n} \leq f(\omega) < \frac{k+1}{2^n}\}, \quad 0 \leq k \leq n2^n,$$ \hspace{1cm} (1.4)

and the sets on the RHS are all measurable. To see that $(f_n)$ is increasing in $n$, we use the inequality

$$\frac{\lfloor 2^n (f \wedge n) \rfloor}{2^n} \leq \frac{\lfloor 2^n (f \wedge (n+1)) \rfloor}{2^n} \leq \frac{\lfloor 2^{n+1} (f \wedge (n+1)) \rfloor}{2^{n+1}},$$

where the second “≤” follows from $\lfloor 2x \rfloor \geq 2\lfloor x \rfloor$. Finally, we show that $f_n \to f$ pointwise.

Fix $\omega \in \Omega$. If $f(\omega) = \infty$, then $f_n(\omega) = n \to f(\omega)$. Suppose $f(\omega) < \infty$. Let $\varepsilon > 0$. We may choose $N$ such that $N > f(\omega)$ and $\frac{1}{2^N} < \omega$. For $n \geq N$, by (1.4), we get the inequality $|f_n(\omega) - f(\omega)| \leq \frac{1}{2^N} < \varepsilon$. \hfill $\Box$

We say that two measurable spaces $(S, \mathcal{S})$ and $(T, \mathcal{T})$ are Borel isomorphic if there is a bijection $f : S \to T$ such that both $f$ and $f^{-1}$ are measurable. This means that $f^{-1}\mathcal{T} = \mathcal{S}$ and $f\mathcal{S} = \mathcal{T}$. A space $S$ that is Borel isomorphic to a Borel subset $I$ of $[0, 1]$, equipped with the Borel $\sigma$-algebra $\mathcal{B}(I) = I \cap \mathcal{B}([0, 1])$, is called a Borel space. By the following lemma, a Polish space is a Borel space.
Definition. A Polish space is a topological space, which admits a separable and complete metrization.

Lemma A1.6. A Polish space $S$ is a Borel space.

Sketch of the proof. The first step is to construct a continuous and injective function $f : S \to [0, 1]^\infty$. Let $(s_n)$ be a dense sequence in $S$. Then we define $f(x) = (1 \land \rho(x, s_n))$. The second step is to use binary expansions to construct a measurable injective function $g : [0, 1]^\infty \to [0, 1]$. See Chapter 13 of Dudley, R.M.’s “Real Analysis and Probability” for details.

For two functions $f : \Omega \to (S, \mathcal{F})$ and $g : \Omega \to (T, \mathcal{T})$, where $(S, \mathcal{F})$ and $(T, \mathcal{T})$ are measurable spaces, we say that $f$ is $g$-measurable if $\sigma(f) \subset \sigma(g)$, or equivalently, $f^{-1} \mathcal{F} \subset g^{-1} \mathcal{T}$. If there is a $(\mathcal{T}/\mathcal{F})$-measurable map $h : T \to S$ such that $f = h \circ g$, then

$$f^{-1} \mathcal{F} = h^{-1}g^{-1} \mathcal{F} \subset g^{-1} \mathcal{T}.$$ 

So $f$ is $g$-measurable. Under some mild conditions, the converse is also true.

Lemma 1.13. Under the above setup, if $(S, \mathcal{F})$ is a Borel space, then $f$ is $g$-measurable if and only if there exists some measurable map $h : T \to S$ such that $f = h \circ g$.

Proof. We only need to show the “only if” part. Since $S$ is Borel, we may assume that $S \in \mathcal{B}([0, 1])$. We may then view $f$ as a map from $\Omega$ into $[0, 1]$. This new viewpoint does not change $\sigma(f)$. So $f$ is still $g$-measurable. If in this case, there exists a measurable map $h : T \to [0, 1]$ such that $f = h \circ g$. Then we may define $h$ such that $h = h$ on $\tilde{h}^{-1}(S)$, and $h = s_0$ on $\tilde{h}^{-1}([0, 1] \setminus S)$, where $s_0$ is a fixed point in $S$. Then $h : T \to S$ is measurable, and $f = h \circ g$. Thus, it suffices to assume that $S = [0, 1]$.

If $f = 1_A$, and $A \in \sigma(g)$, then $A = g^{-1}B$ for some $B \in \mathcal{T}$. So $f = 1_B \circ g$ and we may choose $h = 1_B$. The result extends by linearity to any $g$-measurable simple functions. In the general case, by Lemma 1.11, there exists a sequence of $g$-measurable simple functions $f_n : \Omega \to [0, 1]$ such that $f_n \uparrow f$. For each $n$, there exists an $\mathcal{T}$-measurable map $h_n : T \to [0, 1]$ such that $f_n = h_n \circ g$. Then $h := \sup_n h_n : T \to [0, 1]$ is also $\mathcal{T}$-measurable by Lemma 1.9. Finally, we note that

$$h \circ g = (\sup_n h_n) \circ g = \sup_n (h_n \circ g) = \sup_n f_n = f.$$

Definition. A measure on a measurable space $(\Omega, \mathcal{A})$ is a map $\mu : \mathcal{A} \to \mathbb{R}_+$, which satisfies $\mu(\emptyset) = 0$ and

$$\mu\left(\bigcup_n A_n\right) = \sum_n \mu A_n, \quad \text{for all mutually disjoint } A_1, A_2, \cdots \in \mathcal{A}. \quad (1.5)$$

The triple $(\Omega, \mathcal{A}, \mu)$ is then called a measure space. The measure $\mu$ is called finite if $\mu \Omega < \infty$, and is called a probability measure if $\mu \Omega = 1$. In the latter case, $(\Omega, \mathcal{A}, \mu)$ is called a probability space. The $\mu$ is called a $\sigma$-finite measure if there is a sequence $A_1, A_2, \cdots \in \mathcal{A}$ such that $\Omega = \bigcup_n A_n$ and $\mu A_n < \infty$ for each $n$. 

9
Remark. The property (1.5) is called \textit{countably additivity}, which clearly implies \textit{finitely additivity}:

\[
\mu \bigcup_{n=1}^{N} A_n = \sum_{n=1}^{N} \mu A_n, \quad \text{for all mutually disjoint } A_1, A_2, \ldots A_n \in \mathcal{A},
\]

by setting \( A_n = \emptyset \) for \( n > N \), and \textit{countably subadditivity}:

\[
\mu \bigcup_{n} B_n \leq \sum_{n} \mu B_n, \quad \text{for all } B_1, B_2, \cdots \in \mathcal{A},
\]

by defining \( A_n = B_n \setminus \bigcup_{k<n} B_k \).

**Lemma 1.14 (Continuity).** Let \( \mu \) be a measure on \((\Omega, \mathcal{A})\), and let \( A_1, A_2, \cdots \in \mathcal{A} \).

(i) If \( A_n \uparrow A \), then \( \mu A_n \uparrow \mu A \).

(ii) If \( A_n \downarrow A \), and \( \mu A_1 < \infty \), then \( \mu A_n \downarrow \mu A \).

**Proof.** (i) We apply (1.5) to \( D_n = A_n \setminus A_{n-1} \) with \( A_0 = \emptyset \). (ii) We apply (i) to \( B_n = A_1 \setminus A_n \).

Since \( \mu A_1 < \infty \), we have \( \mu A_n < \infty \) as well, and \( \mu B_n = \mu A - \mu A_n \downarrow \mu A_1 - \mu A \). \( \square \)

**Exercise.** Suppose \( \mu : \mathcal{A} \to \mathbb{R}_+ \) satisfies finitely additivity and the property that if \( B_1 \supset B_2 \supset \cdots \in \mathcal{A} \), and there is \( \varepsilon > 0 \) such that \( \mu B_n \geq \varepsilon > 0 \) for all \( n \), then \( \bigcap_n B_n \neq \emptyset \). Prove that \( \mu \) is a measure.

**Exercise.** Prove that for two measures \( \mu \) and \( \nu \) on \((\Omega, \mathcal{A})\) with \( \mu \Omega = \nu \Omega < \infty \), the class \( \mathcal{D} = \{ A \in \mathcal{A} : \mu A = \nu A \} \) is a \( \lambda \)-system.

By monotone class theorem and the above exercise, we conclude that if two probability measures on \((\Omega, \mathcal{A})\) agree on a \( \pi \)-system \( \mathcal{C} \) with \( \sigma(\mathcal{C}) = \mathcal{A} \), then the two measures must agree.

We may do the following operations on measures. If \( \mu \) is a measure, and \( c \in \mathbb{R}_+ \), then \( c\mu \) is also a measure. If \( \mu \) is finite, then \( \frac{1}{\mu} \mu \) is a probability measure. The sum of two measures is a measure. If \( (\mu_n) \) is an increasing sequence of measures, then \( \lim \mu_n \) is also a measure; if \( (\mu_n) \) is a decreasing sequence of measures, and \( \mu_1 \) is finite, then \( \lim \mu_n \) is also a measure (Lemma 1.15). Thus, if \( \mu_1, \mu_2, \ldots \) are measures on the same space, then \( \sum_n \mu_n \) is a measure.

If \( \mu \) is a measure on \((\Omega, \mathcal{A})\) and \( B \in \mathcal{A} \), then \( \mu(\cdot \cap B) : \mathcal{A} \ni A \mapsto \mu(A \cap B) \) is also a measure on \((\Omega, \mathcal{A})\). It is called the restriction of \( \mu \) to \( B \). One may also view the restriction as a measure on the measurable subspace \( (B, B \cap \mathcal{A}) \).

The simplest measure is the zero measure, which takes value zero at all \( A \in \mathcal{A} \). Another natural measure is the counting measure: \( \mu A = \#(A) \) if \( A \) is finite; \( \mu A = \infty \) if otherwise. For \( s \in \Omega \), the \textit{Dirac measure} (also called point mass) \( \delta_s \) is defined by \( \delta_s(A) = 1 \) if \( s \in A \), and \( \delta_s(A) = 0 \) if otherwise.

The most important nontrivial measure is the \textit{Lebesgue measure} \( \lambda \). It is the unique measure on \((\mathbb{R}, \mathcal{B})\) such that for any interval \( I \), \( \lambda I \) equals \( |I| \), the length of \( I \). It is \( \sigma \)-finite because \( \mathbb{R} = \bigcup_{n \in \mathbb{Z}} [n, n + 1) \). The proof uses the Carathéodory extension theorem stated below.
We call a class \( \mathcal{R} \subset 2^\Omega \) a ring if it contains \( \emptyset \) and is closed under finite union and difference, i.e., \( A, B \in \mathcal{R} \) implies that \( A \cup B, A \setminus B \in \mathcal{R} \). A map \( \mu : \mathcal{R} \to \mathbb{R}_+ \) is called a pre-measure if \( \mu \emptyset = 0 \) and \( \mu \) satisfies countably additivity, i.e., if \( A_1, A_2, \ldots \in \mathcal{R} \) is a partition of \( A \in \mathcal{R} \), then \( \mu A = \sum_n \mu A_n \). By considering the sets \( B_n = A \setminus \bigcup_{k=1}^n B_k \), we find that countably additivity is equivalent to the combination of finitely countability and the statement that for any \( B_1 \supset B_2 \supset \cdots \in \mathcal{R} \), if \( |A| > 0 \) then \( \mu B_n \geq \varepsilon \) for all \( n \), then we have \( \bigcap_n B_n \neq 0 \). If \( \mathcal{R} \) has a partition \( A_1, A_2, \ldots \in \mathcal{R} \) such that \( \mu A_n < \infty \) for each \( n \), then \( \mu \) is called \( \sigma \)-finite.

**Theorem** (Carathéodory extension theorem). A pre-measure \( \mu \) on a ring \( \mathcal{R} \) extends to a measure on \( \sigma(\mathcal{R}) \). The extension is unique if \( \mu \) is \( \sigma \)-finite.

We will only give a sketch of the proof of Carathéodory extension theorem, but will provide details of the application of the theorem in constructing the Lebesgue measure because similar arguments will be used later.

**Proof of Carathéodory extension theorem (Sketch).** The uniqueness part follows from a monotone class argument. Note that for any \( n \), the class \( A_n \in \mathcal{R} \) is a \( \pi \)-system in \( A_n \), and if \( \mu_1 \) and \( \mu_2 \) are two extensions, then the set of \( B \in A_n \cap \sigma(\mathcal{R}) \) such that \( \mu_1 B = \mu_2 B \) form a \( \lambda \)-system in \( A_n \). The existence part uses outer measures. For every \( A \subset \Omega \), we define the outer measure of \( A \) by

\[
\mu^* A = \inf_{I \supseteq A} \mu I.
\]

It is clear that \( \mu^* = \mu \) on \( \mathcal{R} \). Then we consider the set \( \mathcal{F} \) of all \( A \subset \Omega \) such that for every \( E \subset \Omega \)

\[
\mu^*(E) = \mu^*(E \cap A) + \mu^*(E \setminus A).
\]

Then one can prove the following statements:

(i) \( \mathcal{F} \) is a \( \sigma \)-algebra containing \( \mathcal{R} \);

(ii) \( \mu^* \) restricted to \( \mathcal{F} \) is a measure.

By (i), \( \mathcal{F} \subset \sigma(\mathcal{R}) \). By (ii), \( \mu^*|_{\sigma(\mathcal{R})} \) is the extension that we want.

To construct Lebesgue measure, we define a ring \( \mathcal{R} \subset \mathbb{R} \) to be the class of finite disjoint unions of intervals of the form \( (a, b] \), where \( a < b \in \mathbb{R} \). For an element \( A \in \mathcal{R} \) expressed as disjoint union \( \bigcup_{k=1}^n (a_k, b_k] \), we define \( \mu A = \sum_{k=1}^n (b_k - a_k) \). It is easy to check that \( \mu \) satisfies finitely additivity. Then we need to show that, if \( A_1 \supset A_2 \supset \cdots \subset \mathcal{R} \), and \( \mu A_n \geq \varepsilon > 0 \) for all \( n \), then \( \bigcap_n A_n \neq 0 \). For each \( n \), we may pick \( A_n \in \mathcal{R} \) such that \( A_n \subset A_n \) and \( \mu(A_n \setminus A_n) < \varepsilon/2^n \) (if \( A_n = \bigcup_{k=1}^n (a_k, b_k] \), we set \( A_n' = \bigcup_{k=1}^n [a_k', b_k] \) such that \( a_k < a_k' < b_k \) and \( a_k' - a_k \) is small enough). Let \( A_n'' = \bigcap_{k=1}^n A_n' \). Then \( A_n'' \subset A_n \) for each \( n \), and \( A_n'' \supset A_n' \supset \cdots \). Since \( A_n \setminus A_n'' \subset \bigcup_{k=1}^n (A_k \setminus A_k') \), we get \( \mu(A_n \setminus A_n'') \leq \sum_{k=1}^n \mu(A_k \setminus A_k') < \sum_{k=1}^n \frac{\varepsilon/2^n}{2^n} < \varepsilon \). From \( \mu A_n > 0 \) we get \( \mu A_n'' > 0 \), and so \( A_n'' \neq 0 \). Since each \( A_n'' \) is compact and \( A_1'' \supset A_2'' \supset \cdots \), we get \( \bigcap_n A_n'' \neq 0 \), which together with \( A_n'' \subset A_n \) implies that \( \bigcap_n A_n \neq 0 \). So \( \mu \) is a pre-measure on \( \mathcal{R} \). We may then use Carathéodory extension theorem to extend \( \mu \) to a measure on \( \mathbb{R} \). It is easy to check that the extension is the Lebesgue measure.
**Lemma 1.16** (Regularity). Let $\mu$ be a finite measure on some metric space $S$. Then for any $B \in B(S)$,

$$
\mu B = \sup_{F \subseteq B} \mu F = \inf_{G \supset B} \mu G,
$$

(1.6)

with $F$ and $G$ restricted to the classes of closed and open subsets of $S$, respectively.

**Proof.** Let $\mathcal{C}$ denote the set of $B$ which satisfies (1.6). Then (i) $S \in \mathcal{C}$ because $S$ is both closed and open; (ii) $B \in \mathcal{C}$ implies that $B^c \in \mathcal{C}$ since $F \subseteq B$ and $F$ is closed if and only if $F^c \supset B^c$ and $F^c$ is open; (iii) $B^1, B^2 \in \mathcal{C}$ implies that $B^1 \cup B^2 \in \mathcal{C}$ because if for $j = 1, 2$, closed sets $F_n^j \subseteq B_j$, $n \in \mathbb{N}$, satisfy $\mu F_n^1 \to \mu B^1$ and open sets $G_n^1 \supset B^1$, $n \in \mathbb{N}$, satisfy $\mu G_n^1 \to \mu B^1$, then $\mu(F_n^1 \cup F_n^2) \to \mu(B^1 \cup B^2)$ and $\mu(G_n^1 \cup G_n^2) \to \mu(B^1 \cup B^2)$. The first follows from

$$(B^1 \cup B^2) \setminus (F_n^1 \cup F_n^2) \subseteq (B^1 \setminus F_n^1) \cup (B^2 \setminus F_n^2),$$

and the second is similar. The (ii) and (iii) together imply that $\mathcal{C}$ is closed under difference. Suppose $(B_n)$ is an increasing sequence in $\mathcal{C}$, and $B = \bigcup_n B_n$. Fix any $\varepsilon > 0$. We may first choose $n$ such that $\mu B_n > \mu B - \varepsilon / 2$, and then choose closed $F \subseteq B_n$ such that $\mu F > \mu B_n - \varepsilon / 2$. Since $F \subseteq B$ and $\mu F > \mu B - \varepsilon$, we get $\mu B = \sup_{F \subseteq B} \mu F$. On the other hand, for each $n \in \mathbb{N}$, we may choose open $G_n \supset B_n$ such that $\mu G_n < \mu B_n + \frac{\varepsilon}{2^n}$. Let $G = \bigcup_n G_n$. Then $G$ is open, $G \supset B$, and $\mu(G \setminus B) < \sum_n \frac{\varepsilon}{2^n} = \varepsilon$. Thus, $\mu B = \inf_{G \supset B} \mu G$. So $B \in \mathcal{C}$. Hence $\mathcal{C}$ is a $\lambda$-system. We also know that $\mathcal{C}$ contains all open sets since every open set $G$ can be written as a union of an increasing sequence of closed sets. By monotone class theorem, $\mathcal{C}$ contains the Borel $\sigma$-algebra $B(S)$, i.e., (1.6) holds for any $B \in B(S)$. \qed

Let $\mu$ be a measure on $(S, \mathcal{S})$, and $f$ is a measurable map from $(S, \mathcal{S})$ into $(T, \mathcal{T})$, then we get a measure $\mu \circ f^{-1}$ (also denoted by $f_* \mu$) on $(T, \mathcal{T})$ defined by

$$(\mu \circ f^{-1})A = \mu f^{-1}A.$$

It is called the pushforward of $\mu$ under $f$.

Given a measure space $(\Omega, \mathcal{A}, \mu)$, we are going to define the integral

$$
\mu f = \int f d\mu = \int f(\omega)\mu(d\omega)
$$

for certain real valued measurable function $f$ on $(\Omega, \mathcal{A})$. The construction is composed of several steps.

**Step 1.** If $f$ is a nonnegative measurable simple function of the form

$$f = c_1 \mathbf{1}_{A_1} + \cdots + c_n \mathbf{1}_{A_n}$$

with $c_1, \ldots, c_n \in \mathbb{R}^+$ and $A_1, \ldots, A_n \in \mathcal{A}$, we define

$$
\mu f = c_1 \mu A_1 + \cdots + c_n \mu A_n.
$$
Throughout measure theory we follow the convention that $0 \cdot \infty = 0$. Using the finite additivity of $\mu$, one can show that the definition is consistent, i.e., if $f$ has another expression: $d_1 \mathbf{1}_{B_1} + \cdots + d_m \mathbf{1}_{B_m}$, then $d_1 \mu(B_1) + \cdots + d_m \mu(B_m)$ equals the same number. We then get linearity and monotonicity: for nonnegative measurable simple functions $f$ and $g$:

$$\mu(af + bg) = a\mu f + b\mu g, \quad \text{for } a, b \geq 0; \quad (1.7)$$

$$\mu f \geq \mu g \geq 0, \quad \text{if } f \geq g. \quad (1.8)$$

**Exercise.** Check the consistency and formulas $(1.7)$ and $(1.8)$.

**Step 2.** If $f : \Omega \to \mathbb{R}_+$ is measurable, by Lemma 1.11 we may choose a sequence of nonnegative measurable simple functions $(f_n)$ such that $f_n \uparrow f$. Then we define

$$\mu f = \lim \mu f_n.$$

We also need to prove the consistency, i.e., the definition does not depend on the choice of $(f_n)$.

**Lemma 1.18.** Let $f_1, f_2, \cdots$ and $g$ be simple measurable functions on $\Omega$ such that $0 \leq f_1 \leq f_2 \leq \cdots$ and $0 \leq g \leq \lim f_n$. Then $\lim \mu f_n \geq \mu g$.

**Proof.** First suppose $g = c\mathbf{1}_A$ for $c \in \mathbb{R}_+$ and $A \in \mathcal{A}$. If $c = 0$, it is trivial. For $c > 0$, fix $\epsilon \in (0, c)$ and let $A_n = A \cap \{f_n \geq c - \epsilon\}$. Then $A_n \uparrow A$, and so

$$\mu f_n \geq \mu(c - \epsilon)\mathbf{1}_{A_n} = (c - \epsilon)\mu A_n \uparrow (c - \epsilon)\mu A.$$

So $\lim \mu f_n \geq (c - \epsilon)\mu A$. Letting $\epsilon \to 0$, we get $\lim \mu f_n \geq c\mu A = \mu g$.

Now suppose $g = c_1\mathbf{1}_{A_1} + \cdots c_m\mathbf{1}_{A_m}$ with $c_1, \ldots, c_m \in \mathbb{R}_+$ and $A_1, \ldots, A_m \in \mathcal{A}$. We may assume that $A_1, \ldots, A_m$ are mutually disjoint. Let $\mu_k = \mu(\cdot \cap A_k)$, $1 \leq k \leq m$, and

$$\mu = \sum_{k=0}^{n} \mu_k.$$ 

Then $\mu f_n \geq \sum_{k=1}^{m} \mu_k f_n$. For $1 \leq k \leq m$, since $\lim f_n \geq g \geq c_k \mathbf{1}_{A_k}$, by the above paragraph we get $\lim \mu_k f_n \geq c_k \mu A_k$. Thus,

$$\lim_{n} \mu f_n \geq \lim_{n} \sum_{k=1}^{m} \mu_k f_n = \sum_{k=1}^{m} \lim_{n} \mu_k f_n \geq \sum_{k=1}^{m} c_k \mu A_k = \mu g.$$

Applying this lemma, we see that if $(f_n)$ and $(g_m)$ are two sequences of measurable simple functions with $0 \leq f_n \uparrow f$ and $0 \leq g_m \uparrow f$, then for each $m$, $\lim_{n} \mu f_n \geq \mu g_m$. So $\lim_{n} \mu f_n \geq \lim_{m} \mu g_m$. By symmetry, we have $\lim_{m} \mu g_m \geq \lim_{n} \mu f_n$. So $\lim_{n} \mu f_n = \lim_{m} \mu g_m$, and we get the consistency in the definition of $\mu f$.

We can easily prove the linearity and monotonicity: for measurable functions $f$ and $g$ from $\Omega$ into $\mathbb{R}_+$, $(1.7)$ and $(1.8)$ both hold.

**Theorem 1.19** (Monotone Convergence Theorem). Let $f_1, f_2, \cdots : (\Omega, \mathcal{A}) \to \mathbb{R}_+$ be measurable. Suppose $f_n \uparrow f$. Then $\mu f_n \uparrow \mu f$. 

13
Proof. For each \( n \), we choose a sequence of measurable simple functions \((g^n_k)\) such that \( g^n_k \uparrow f_n \) as \( k \to \infty \). Then \( \mu f_n = \lim_k \mu g^n_k \). Define
\[
h_k = g^1_k \lor g^2_k \lor \cdots \lor g^k_k.
\]
Then \((h_k)\) is an increasing sequence of nonnegative simple measurable functions. Since for each \( k \in \mathbb{N} \), \( h_k \leq f_1 \lor f_2 \lor \cdots \lor f_k = f_k \leq f \), we have \( \lim h_k \leq f \) and
\[
\lim \mu h_k \leq \lim \mu f_k \leq \mu f. \tag{1.9}
\]
For any fixed \( n \in \mathbb{N} \), we have \( h_k \geq g^n_k \) for \( k \geq n \). So \( \lim h_k \geq \lim_k g^n_k = f_n \). Thus, \( \lim h_k \geq \sup f_n = f \). So we get \( h_k \uparrow f \) and \( \mu f = \lim \mu h_k \). By (1.9) we get \( \lim \mu f_k = \mu f \). \qed

Lemma 1.20 (Fatou). For any measurable functions \( f_1, f_2, \cdots : (\Omega, \mathcal{A}) \to \mathbb{R}_+ \), we have
\[
\lim \inf \mu f_n \geq \mu \lim \inf f_n.
\]
Proof. Fix \( n \in \mathbb{N} \). Since \( f_k \geq \inf_{m \geq n} f_m \) for all \( k \geq n \), by monotonicity,
\[
\inf_{k \geq n} \mu f_k \geq \mu \inf_{m \geq n} f_m.
\]
Letting \( n \to \infty \) and using monotone convergence theorem, we get
\[
\lim \inf \mu f_n = \lim_{n} \inf_{k \geq n} \mu f_k \geq \lim_{n} \mu \inf_{m \geq n} f_m = \mu \lim \inf_{n} f_m = \mu \lim \inf f_n.
\]

Step 3. We define \( \mu f \) for integrable functions. A measurable function \( f : (\Omega, \mathcal{A}, \mu) \to \mathbb{R} \) is called integrable if \( \mu|f| < \infty \). Here since \( |f| \) is a nonnegative measurable function, \( \mu|f| \) was defined in Step 2. For the definition, we find two nonnegative measurable functions \( f_1 \) and \( f_2 \) such that \( f = f_1 - f_2 \) and \( \mu f_1, \mu f_2 < \infty \), and then let
\[
\mu f = \mu f_1 - \mu f_2.
\]
For the existence of such \( f_1 \) and \( f_2 \), we may let \( f_1 = f_+ := f \lor 0 \) and \( f_2 = f_- := (-f) \lor 0 \). In fact, we have \( f_+, f_- \geq 0, f = f_+ - f_- \), and \( |f| = f_+ + f_- \). So \( 0 \leq f_\pm \leq |f| \), which implies that \( \mu f_\pm \leq \mu|f| < \infty \). For the consistency, suppose \( g_1 \) and \( g_2 \) satisfy the same properties as \( f_1 \) and \( f_2 \). Then from \( f_1 - f_2 = g_1 - g_2 \) we get \( f_1 + g_2 = g_1 + f_2 \), and so \( \mu f_1 + \mu g_2 = \mu g_1 + \mu f_2 \). Since every item is a real number, we get \( \mu f_1 - \mu f_2 = \mu g_1 - \mu g_2 \). Thus, \( \mu f \) is well defined. Finally, since \( \mu f = \mu f_+ - \mu f_- \) and \( |f| = \mu f_+ + \mu f_- \), we get \( |\mu f| \leq |f| \).

We then have the monotonicity and the linearity with real coefficient: if \( f, g : \Omega \to \mathbb{R} \) are integrable, and \( a, b \in \mathbb{R} \), then \( af + bg \) is also integrable, and \( \mu(af + bg) = a\mu f + b\mu g \).

In summary, the integral \( \mu f \) is defined for (i) all measurable functions \( f : (\Omega, \mathcal{A}, \mu) \to \mathbb{R}_+ \); and (ii) all measurable functions \( f : (\Omega, \mathcal{A}, \mu) \to \mathbb{R} \) such that \( \mu|f| < \infty \). In the former case, \( \mu f \) takes values in \( \mathbb{R}_+ \), and in the latter case, \( \mu f \) takes values in \( \mathbb{R} \).
Theorem 1.21 (Dominated Convergence). Let \( f, f_1, f_2, \ldots \) and \( g, g_1, g_2, \ldots \) be \( \mathbb{R} \)-valued measurable functions on \((\Omega, \mathcal{A}, \mu)\) with \( |f_n| \leq g_n \) for all \( n \), and such that \( f_n \to f \), \( g_n \to g \), and \( \mu g_n \to \mu g < \infty \). Then \( \mu f_n \to \mu f \).

Proof. The sequence \((g_n \pm f_n)\) are nonnegative measurable functions and \( g_n \pm f_n \to g \pm f \). Since \( \mu g < \infty \) and \( \mu g_n \to \mu g \), \( g \) and \( g_n \) are integrable for all but finitely many \( n \). Since \( |f_n| \leq g_n \) and \( |f| \leq g \), the same statement holds for \( g \) and \( f \). By Fatou’s lemma and linearity of integral,

\[
\mu g \pm \mu f = \mu(g \pm f) \leq \lim \inf \mu(g_n \pm f_n) = \lim \inf(\mu g_n \pm \mu f_n) = \mu g + \lim \inf(\pm \mu f_n).
\]

So we get \( \mu f \leq \lim \inf \mu f_n \) and \( -\mu f \leq \lim \inf(-\mu f_n) = -\lim \sup \mu f_n \), which implies that \( \lim \sup \mu f_n \leq \mu f \leq \lim \inf \mu f_n \). So \( \lim \mu f_n = \mu f \). \( \square \)

Lemma 1.22 (Substitution). Let \( f \) from a measurable map from \((\Omega, \mathcal{A}, \mu)\) to \((S, \mathcal{S})\). Let \( \mu \circ f^{-1} \) be the pushforward measure on \((S, \mathcal{S})\). Then for measurable function \( g : S \to \mathbb{R} \),

\[
(\mu \circ f^{-1})g = \mu(g \circ f). \tag{1.10}
\]

Here the equality means that when one side is defined, then the other side is also defined, and the two sides agree.

Proof. We first show that if \( g : S \to \mathbb{R}_+ \), and so \( g \circ f : \Omega \to \mathbb{R}_+ \) and both sides are well defined, then \( (1.10) \) holds. The simplest case is \( g = 1_A \). In this case

\[
(\mu \circ f^{-1})g = (\mu \circ f^{-1})A = \mu f^{-1}A = \mu 1_{f^{-1}A} = \mu(g \circ f).
\]

By linearity, \( (1.10) \) then holds for all nonnegative measurable simple functions. By monotone convergence, \( (1.10) \) also holds for all nonnegative measurable functions.

For measurable \( g : S \to \mathbb{R} \), since \( |g \circ f| = |g| \circ f \), by \( (1.10) \) \( g \) is integrable w.r.t. \( \mu \circ f^{-1} \) if and only if \( g \circ f \) is integrable w.r.t. \( \mu \). Moreover, if \( g = g_1 - g_2 \) such that \( g_1, g_2 : S \to \mathbb{R} \) are measurable and \( (\mu \circ f^{-1})g_j < \infty \), \( j = 1, 2 \), then by applying \( (1.10) \) to \( g_j \) we get \( (1.10) \) for \( g \). \( \square \)

Given a measurable function \( f : (\Omega, \mathcal{A}, \mu) \to \mathbb{R}_+ \), we may define another measure \( f \cdot \mu \) on \((\Omega, \mathcal{A})\) by

\[
(f \cdot \mu)A = \int_A f d\mu = \int 1_A f.
\]

The countably additivity of \( f \cdot \mu \) follows from monotone convergence theorem. The \( f \) is referred as the \( \mu \)-density of \( f \cdot \mu \).

Lemma 1.23 (Chain Rule). For any measurable maps \( f, g : (\Omega, \mathcal{A}, \mu) \to \mathbb{R} \) with \( f \geq 0 \),

\[
(f \cdot \mu)g = \mu(fg).
\]

The meaning of the equality should be explained in the same way as \( (1.10) \), i.e., when one side is define, the other side is also defined, and the two sides agree.
Proof. As in the last proof, we may begin with the case when \( g \) is an indicator function and then extend in steps to the general case. \( \square \)

This lemma implies that, if \( f, g : \Omega \to \mathbb{R}_+ \) are measurable, then \( f \cdot (g \cdot \mu) = (fg) \cdot \mu \).

Given a measure space \( (\Omega, \mathcal{A}, \mu) \), a set \( A \in \mathcal{A} \) is called \( \mu \)-null if \( \mu A = 0 \). A relation depending on \( \omega \in \Omega \) is said to hold \( \mu \)-almost everywhere if there is a \( \mu \)-null set \( A \) such that it holds for all \( \omega \in A^c \). We often write \( \mu \text{-a.e.} \) or simply \( \text{a.e.} \).

**Lemma 1.24.** If \( f, g : (\Omega, \mathcal{A}, \mu) \to \mathbb{R} \) satisfy that \( \mu \text{-a.e. } f = g \), then \( \mu f = \mu g \). Again the equality means that if any of \( \mu f \) and \( \mu g \) is defined, then the other is also defined, and the two values are equal.

**Proof.** First, suppose \( g = 0 \) and \( f \geq 0 \). Let \( (f_n) \) be a sequence of measurable simple functions with \( 0 \leq f_n \uparrow f \). Then \( \{ f_n \neq 0 \} \subset \{ f \neq 0 \} \), and so \( \{ f_n \neq 0 \} \) is a null set. We may express each \( f_n \) as \( c_1 1_{A_1} + \cdots c_m 1_{A_m} \) with \( c_1, \ldots, c_m \in \mathbb{R}_+ \) and \( A_1, \ldots, A_m \) are null sets. Then \( \mu f_n = \sum c_k \mu A_k = 0 \). So \( \mu f = \lim \mu f_n = 0 = \mu g \).

Second, suppose \( f, g \geq 0 \). Let \( h = f \vee g \). Then \( h \geq f \) and \( \mu \text{-a.e.}, h = f \). We may write \( h = f + \phi \), where \( \phi : \Omega \to \mathbb{R}_+ \) is measurable and \( \mu \text{-a.e.}, \phi = 0 \). By the first paragraph, \( \mu \phi = 0 \). So \( \mu h = \mu f + \mu \phi = \mu f \). Similarly, \( \mu h = \mu g \). So \( \mu f = \mu g \).

Now we consider integrable functions. Since \( \mu \text{-a.e.}, \ |f| = |g| \), by the second paragraph, \( \mu |f| = \mu |g| \). So \( f \) is integrable if and only if \( g \) is integrable. Now suppose \( f \) and \( g \) are integrable. Since \( f = (\pm f) \vee 0 = (\pm g) \vee 0 = g \pm \) a.e., by the previous result we have \( \mu f = \mu g \). So \( \mu f = \mu f_+ - \mu f_- = \mu g_+ - \mu g_- = \mu g \). \( \square \)

On the other hand, if \( f : (\Omega, \mathcal{A}, \mu) \to \mathbb{R}_+ \) satisfies that \( \mu f = 0 \), then \( \mu \text{-a.e. } f = 0 \). In fact, since \( \{ f \neq 0 \} = \bigcup_n \{ f \geq 1/n \} \), if \( \mu \{ f \neq 0 \} > 0 \), then there is \( n \in \mathbb{N} \) such that \( \mu \{ f \geq 1/n \} > 0 \). Then we get

\[
\mu f \geq \mu 1_{\{ f \geq 1/n \}} = \frac{1}{n} \mu \{ f \geq 1/n \} > 0.
\]

Since two integrals agree when two integrands agree \( \mu \text{-a.e.} \), we may allow the integrands to be undefined on some \( \mu \)-null sets. Monotone Convergence Theorem, Fatou’s Lemma, and Dominated Convergence Theorem remain valid if the hypothesis are only fulfilled outside some null sets. We also note that if \( f : \Omega \to \mathbb{R}_+ \) satisfies \( \mu f < \infty \), then a.e. \( f \in \mathbb{R}_+ \) because from \( \infty > \mu f \geq \infty \cdot \mu f^{-1} \{ \infty \} \) we get \( \mu f^{-1} \{ \infty \} = 0 \).

**Definition.** Let \( \mu \) and \( \nu \) be two measures on a measurable space \( (\Omega, \mathcal{A}) \). We say that \( \nu \) is absolutely continuous with respect to \( \mu \) and write \( \nu \ll \mu \) if every \( \mu \)-null set is also a \( \nu \)-null set. We say that \( \mu \) and \( \nu \) are mutually singular and write \( \mu \perp \nu \) if there is \( A \in \mathcal{A} \) such that \( \mu A = 0 \) and \( \nu A^c = 0 \).

If \( \nu = f \cdot \mu \), then for any \( \mu \)-null set \( A \), \( \nu A = \int 1_A f d\mu = 0 \) since \( \mu \text{-a.e.}, 1_A f = 0 \). So \( A \) is also a \( \nu \)-null set. Thus, we have \( f \cdot \mu \ll \mu \). We focus on \( \sigma \)-finite measures.

**Theorem A1.3** (Radon-Nikodym). Let \( \mu \) and \( \nu \) are two \( \sigma \)-finite measures on \( (\Omega, \mathcal{A}) \),
(i) If \( \nu \ll \mu \), there is a \( \mu \)-a.e. unique measurable function \( f : \Omega \to \mathbb{R}_+ \) such that \( \nu = f \cdot \mu \).

(ii) In the general case, there is a \( \mu \)-a.e. unique measurable function \( f : \Omega \to \mathbb{R}_+ \) such that \( \sigma := \nu - f \cdot \mu \) is a measure that is singular to \( \mu \).

In Part (i) of the theorem, we also call \( f \) the Radon-Nikodym derivative of \( \nu \) against \( \mu \). For the proof of Radon-Nikodym Theorem, we introduce the notation of real measures, which is important on its own.

**Definition**. Let \((\Omega, \mathcal{A})\) be a measurable space. A function \( \nu : \mathcal{A} \to \mathbb{R} \) is called a real measure or signed measure if it satisfies countably additivity with \( \nu(\emptyset) = 0 \), i.e., if \( A_1, A_2, \cdots \in \mathcal{A} \) are mutually disjoint, then \( \nu(\bigcup_n A_n) = \sum_n \nu(A_n) \), where the series converges absolutely.

A finite measure is a real measure, and the space of all real measures on \((\Omega, \mathcal{A})\) is a linear space. Thus, the difference of two finite measures is a real measure. If \( \mu \) is a measure, and \( f : \Omega \to \mathbb{R} \) is integrable with respect to \( \mu \), then \( (f \cdot \mu)(A) := \int_A f \, d\mu \) is a real measure. The countably additivity follows from the Dominated Convergence Theorem.

A real measure \( \nu \) satisfies continuity: if \( A_n \uparrow A \) or \( A_n \downarrow A \), then \( \nu A_n \to \nu A \). Actually, if \( A_n \uparrow A \), we may write \( A = \bigcup_n (A_n \setminus A_{n-1}) \) with \( A_0 = \emptyset \). Since \( A_n \setminus A_{n-1} \) are mutually disjoint, \( \nu = \sum_n \nu(A_n \setminus A_{n-1}) = \sum_n (\nu A_n - \nu A_{n-1}) = \lim \nu A_n \). If \( A_n \downarrow A \), then \( A_n^c \uparrow A^c \) and \( \nu A^c = \nu \Omega - \nu A \).

**Theorem** (Hahn decomposition). Given a real measure \( \nu \) on \((\Omega, \mathcal{A})\), there exists a partition \( \{P, N\} \) of \( \Omega \) such that \( P, N \in \mathcal{A} \), \( \nu E \geq 0 \) for all \( E \in P \cap \mathcal{A} \), and \( \nu E \leq 0 \) for all \( E \in N \cap \mathcal{A} \).

**Proof.** Let \( s = \sup \{\nu A : A \in \mathcal{A}\} \). Then \( s \geq 0 \) since \( \nu \emptyset = 0 \). We now exclude the possibility that \( s = +\infty \). Suppose \( s = +\infty \). Let

\[
B = \{A \in \mathcal{A} : \sup \{\nu B : B \in \mathcal{A}, B \subset A\} = +\infty\}.
\]

Then \( \Omega \in B \). It is also easy to see that if \( A_1, A_2 \in \mathcal{A} \setminus B \) and \( A_1 \cap A_2 = \emptyset \), then \( A_1 \cup A_2 \in \mathcal{A} \setminus B \). Thus, if \( A_1 \in B, A_2 \in \mathcal{A} \setminus B \), and \( A_2 \subset A_1 \), then \( A_1 \setminus A_2 \in B \). First, suppose

\[
\sup \{\nu B : B \in B, B \subset A\} = +\infty, \quad \forall A \in B. \tag{1.11}
\]

Then we can inductively construct a sequence \( A_0 \supset A_1 \supset A_2 \supset \cdots \) in \( B \) with \( A_0 = \Omega \) and \( \nu A_{n+1} > \nu A_n \). Then \( (\nu A_n) \) does not converge, which contradicts the continuity of \( \nu \). Second, suppose \([1.11]\) does not hold. Then there exist \( A_0 \in B \) and \( M \in (0, \infty) \) such that for any \( B \in B \) with \( B \subset A_0 \), we have \( \nu B \leq M \). We inductively choose a sequence of mutually disjoint sets \( \{A_n\} \) in \( A_0 \cap \mathcal{A} \) such that \( \nu A_n > M \) for each \( n \). First, since \( A_0 \in B \), we may choose \( A_1 \in \mathcal{A} \) such that \( \nu A_1 > M \). Since \( \nu B \leq M \) for any \( B \in B \) with \( B \subset A_0 \), we see that \( A_1 \in \mathcal{A} \setminus B \). So \( A_0 \setminus A_1 \in B \). Suppose we have found mutually disjoint sets \( A_1, \ldots, A_k \in A_0 \cap \mathcal{A} \) such that \( A_0 \setminus \bigcup_{k=1}^k A_k \in B \) (this is the case for \( n = 1 \)). Then by the definition of \( B \), we can find \( A_{n+1} \in \mathcal{A} \) with \( A_{n+1} \subset A_0 \setminus \bigcup_{k=1}^n A_k \) and \( \nu A_{n+1} \geq M \). Now \( A_1, \ldots, A_{n+1} \) are mutually disjoint. Since
$A_{n+1} \subset A$, we get $A_{n+1} \in A \setminus B$. Thus, $A_0 \setminus \bigcup_{k=1}^{n+1} A_k = (A_0 \setminus \bigcup_{k=1}^n A_k) \setminus A_{n+1} \in B$. So the sequence $(A_n)$ is constructed. However, by the countably additivity of $\nu$, we should have $\nu A_n \to 0$, which is a contradiction. Thus, $s < +\infty$.

For any $A, B \in A$, we have by inclusion-exclusion,

$$\nu(A \cap B) = \nu A + \nu B - \nu(A \cup B) \geq \nu A + \nu B - s.$$ 

So $s - \nu A \cap B \leq (s - \nu A) + (s - \nu B)$. By induction, we have

$$s - \nu \bigcap_{k=1}^n A_k \leq \sum_{k=1}^n (s - \nu A_k), \quad A_1, \ldots, A_n \in A.$$ 

If $A_1, A_2, \ldots$ is a sequence in $A$, then by continuity $\nu \bigcap_{n=1}^\infty A_n = \lim_{n} \nu \bigcap_{k=1}^n A_k$. So

$$s - \nu \left( \bigcap_{n} A_n \right) \leq \sum_{n} (s - \nu A_n), \quad (1.12)$$ 

By the definition of $s$, there is a sequence $A_1, A_2, \ldots \in A$ such that $\nu A_n > s - \frac{1}{2^n}$ for each $n$. Define an increasing sequence $(B_n)$ by $B_n = \bigcap_{m=n}^\infty A_m$. By (1.12),

$$\nu B_n \geq s - \sum_{k=n}^{\infty} \frac{1}{2^k} = s - \frac{1}{2^{n-1}}, \quad n \in \mathbb{N}. \quad (1.13)$$

Let $P = \bigcup_{n} B_n$ and $N = P^c$. Then $\{P, N\}$ is a measurable partition of $\Omega$. By continuity of $\nu$ and (1.13), $\nu P = \lim_\nu B_n \geq s$. By the definition of $s$, $\nu P \leq s$. So $\nu P = s$. If there is $E \in P \cap A$ such that $\nu E < 0$, then $\nu(P \setminus E) = \nu P - \nu E > \nu P = s$, which contradicts the definition of $s$. So $\nu E \geq 0$ for any $E \in A$ with $E \subset C$. If there is $E \in N \cap A$ such that $\nu E > 0$, then $\nu(P \cup E) = \nu P + \nu E > \nu P = s$, which again contradicts the definition of $s$. So $\nu E \geq 0$ for any $E \in A$ with $E \subset C$.

If we set $\nu_+ = \nu(\cdot \cap P)$ and $\nu_- = -\nu(\cdot \cap N)$, then $\nu_+$ and $\nu_-$ are two finite (nonnegative) measures, and $\nu = \nu_+ - \nu_-$. Since $\nu_+ P^c = \nu_- P = 0$, we have $\nu_+ \perp \nu_-$. We call $\nu = \nu_+ - \nu_-$ the Jordan decomposition of $\nu$.

**Lemma**. The Jordan decomposition of a real measure is unique.

**Proof**. We leave this as an exercise.

If $\nu_+ - \nu_-$ is the Jordan decomposition of a real measure $\nu$, then we define the measure $|\nu| = \nu_+ + \nu_-$, and call it the total variation of $\nu$.

**Proof of Radon-Nikodym Theorem.** (i) The uniqueness part is easy. If $\nu = f \cdot \mu = g \cdot \mu$, and $\mu\{f \neq g\} > 0$, then $\mu\{f > g\} > 0$ or $\mu\{g > f\} > 0$. By symmetry we assume that $\mu\{f > g\} > 0$. Then there is $n \in \mathbb{N}$ such that $\mu\{f > g + 1/n\} > 0$. Then $f \cdot \mu$ does not agree with $g \cdot \mu$ on $\{f > g + 1/n\}$, a contradiction.
For the existence, we may assume that $\mu$ and $\nu$ are finite. This is because we may find a measurable partition $\{A_n : n \in \mathbb{N}\}$ of $\Omega$ such that $\mu A_n, \nu A_n < \infty$ for each $n$. Then $\mu_n := \mu(\cdot \cap A_n)$ and $\nu_n := \nu(\cdot \cap A_n)$ are finite measures with $\nu_n \ll \mu_n$ for each $n$. If for each $n$, $\nu_n = f_n \cdot \mu_n$ for some $f_n : A_n \to \mathbb{R}_+$, then we may construct the $\mu$-density $f$ of $\nu$ with $f|_{A_n} = f_n$.

Now $\mu$ and $\nu$ are finite measures. Let $F$ be the set of measurable functions $f : \Omega \to \mathbb{R}_+$ such that $f : \mu \leq \nu$, i.e., $\nu A \geq (f \cdot \mu)A$ for all $A \in \mathcal{A}$. Here $F$ contains $0$. For $f_1, f_2 \in F$, let $A_1 = \{f_1 > f_2\}$ and $A_2 = \{f_1 \leq f_2\}$. For any $A \in \mathcal{A}$,

$$\int_A f_1 \vee f_2 d\mu = \int_{A \cap A_1} f_1 d\mu + \int_{A \cap A_2} f_2 d\mu \leq \nu A \cap A_1 + \nu A \cap A_2 = \nu A.$$  

So $f_1 \vee f_2 \in F$. Let $s = \sup \{|f| : f \in F\}$. Then $0 \leq s \leq \nu \Omega < \infty$. We may find a sequence $g_1, g_2, \ldots \in F$ such that $\mu g_n \to s$. Let $f_n = g_1 \vee \cdots \vee g_n$, $n \in \mathbb{N}$. Then $(f_n)$ is increasing, and for each $n$, $f_n \in F$, and $f_n \geq g_n$. So $\mu f_n \to s$. Let $f = \lim f_n$. By monotone convergence theorem, for any $A \in \mathcal{A}$, $\int_A f d\mu = \lim \int_A f_n d\mu \leq \nu A$. So $f \in F$. Moreover, $\mu f = \lim \mu f_n = s$. We claim that $\nu = f \cdot \mu$. If it is not true, then $v_0 := \nu - f \cdot \mu$ is a non-zero measure. Since $\mu$ is finite, there is $\varepsilon > 0$ such that $v_0 \Omega > \varepsilon \mu \Omega$. Now $\tau := v_0 - \varepsilon \mu$ is a real measure with $\tau \Omega > 0$. By Hahn decomposition theorem, there is a partition $\Omega = P \cup N$ such that $\tau(\cdot \cap P)$ and $-\tau(\cdot \cap N)$ are measures. For every $A \in \mathcal{A}$, from $\tau(A \cap P) \geq 0$, we get $v_0(A \cap P) \geq \varepsilon \mu(A \cap P)$, and so

$$\nu A = \int_A f d\mu + v_0 A \geq \int_A f d\mu + \varepsilon \mu A \cap P \geq \int_A f d\mu + \varepsilon \mu A \cap P = \int_A (f + \varepsilon 1_P) d\mu.$$  

Thus, $f + \varepsilon 1_P \in F$. From $s = \mu f \leq \mu (f + \varepsilon 1_P) \leq s$ we get $\mu P = 0$. So $\nu P = v_0 P = \tau P = 0$. Then we see that $-\tau$ is a (positive) measure, which contradicts that $\tau \Omega > 0$. The contradiction shows that $\nu = f \cdot \mu$.

(ii) Let $\tau = \mu + \nu$. Then $\tau$ is also a $\sigma$-finite measure. Since $0 \leq \nu \leq \tau$, we have $\nu \ll \tau$. By (i) there is a measurable $g : \Omega \to \mathbb{R}_+$ such that $\nu = g \cdot \tau$. We have $\tau$-a.e. $g \leq 1$ because for any $A \in \mathcal{A}$, $\int_A 1 - g d\tau = \tau A - (g \cdot \tau)A = \tau A - \nu A = \mu A \geq 0$. By changing the values of $g$ on a $\tau$-null set, we may assume that $0 \leq g \leq 1$. From $\nu = g \cdot \tau$ we get $\mu = (1 - g) \cdot \tau$. Let $A = \{g < 1\}$. Then $\mu A^c = 0$. Define $f = \frac{g}{1 - g}$ on $A$ and $f = 0$ on $A^c$. Then $\nu(\cdot \cap A) = f \cdot \mu$. Let $\sigma = \nu - f \cdot \mu = \nu(\cdot \cap A^c)$. Then $\sigma A = 0$. So $\sigma \perp \mu$.

For the uniqueness, we still let $\tau = \mu + \nu$. Suppose $\nu = f \cdot \mu + \sigma$ for some measurable $f : \Omega \to \mathbb{R}_+$ and some measure $\sigma$ with $\sigma \perp \mu$. Let $A \in \mathcal{A}$ be such that $\mu A^c = \sigma A = 0$. Then

$$\nu = 1_A f \cdot \mu + 1_{A^c} \cdot \sigma, \quad \tau = 1_A (f + 1) \cdot \mu + 1_{A^c} \cdot \sigma.$$  

So $\nu = (1_A \frac{f}{f + 1} + 1_{A^c}) \cdot \tau$. By the uniqueness part of (i), if $\tau = g \cdot \mu + \rho$ and $\mu B^c = \rho B = 0$, then

$$\frac{1_A f}{f + 1} + 1_{A^c} = \frac{1_B - g}{g + 1} + 1_{B^c}, \quad \tau - \text{a.e.}.$$  

This implies that $\tau$-a.e. $1_A f = 1_B g$. Since $\mu A^c = \mu B^c = 0$ and $\mu \ll \tau$, we get $\mu$-a.e. $f = g$. \hfill $\square$
Radon-Nikodym theorem also extends to real measures.

**Corollary.** Let $\mu$ be a $\sigma$-finite measure on $(\Omega, \mathcal{A})$. Let $\nu$ be a real measure on $(\Omega, \mathcal{A})$. Suppose $\nu \ll \mu$, i.e., for any $A \in \mathcal{A}$, $\mu A = 0$ implies $\nu A = 0$. Then there a $\mu$-a.e. unique $f : \Omega \to \mathbb{R}$, which is integrable w.r.t. $\mu$, such that $\nu = f \cdot \mu$.

**Proof.** This follows from the Radon-Nikodym theorem and Jordan decomposition. \hfill \Box

**Example.** (An important application.) Suppose $\mu$ is a probability measure on $(\Omega, \mathcal{A})$, $\mathcal{F}$ is a sub-$\sigma$-algebra of $\mathcal{A}$, and $f : \Omega \to \mathbb{R}$ is $\mathcal{A}$-measurable with $|f| < \infty$. Let $\nu = f \cdot \mu$. Then $\nu$ is a signed measure on $(\Omega, \mathcal{A})$, and $\nu \ll \mu$. Let $\mu' = \mu|_{\mathcal{F}}$ and $\nu' = \nu|_{\mathcal{F}}$. Then $\mu'$ is a probability measure on $(\Omega, \mathcal{F})$, $\nu'$ is a signed measure on $(\Omega, \mathcal{F})$, and $\nu' \ll \mu'$. By the above corollary, there is an $\mathcal{F}$-measurable $f' : \Omega \to \mathbb{R}$ with $|\nu'|f'| < \infty$ such that $\nu' = f' \cdot \mu'$. Then for any $A \in \mathcal{F}$,

$$\int_A f' \, d\mu = \int_A f' \, d\mu' = \nu A = \int_A f \, d\mu.$$ 

Such $f'$ is $\mu$-a.e. unique, and is called the expectation of $f$ conditionally on $\mathcal{F}$ with respect to $\mu$.

A measure space $(\Omega, \mathcal{A}, \mu)$ is called complete if for every $B \subset A \subset \Omega$ with $A \in \mathcal{A}$ and $\mu A = 0$, we have $B \in \mathcal{A}$. Given a measure space $(\Omega, \mathcal{A}, \mu)$, a $\mu$-completion of $\mathcal{A}$ is the $\sigma$-algebra

$$\mathcal{A}^\mu := \sigma(\mathcal{A}, \mathcal{N}_\mu),$$

where $\mathcal{N}_\mu$ is the class of all subsets of $\mu$-null sets in $\mathcal{A}$. Note that $\mathcal{N}_\mu$ is closed under countable union because if $N_1, N_2, \cdots \in \mathcal{N}_\mu$, there are $A_1, A_2, \cdots \in \mathcal{A}$ with $N_n \subset A_n$ and $\mu A_n = 0$ for each $n$. Then $\bigcup_n N_n \subset \bigcup_n A_n \in \mathcal{A}$, and $\mu \bigcup_n A_n = 0$. So $\bigcup_n N_n \in \mathcal{N}_\mu$.

**Lemma 1.25.** (i) A set $A \subset \Omega$ is $\mathcal{A}^\mu$-measurable if and only if there exist $A', A'' \in \mathcal{A}$ with $A' \subset A \subset A''$ and $\mu(A'' \setminus A') = 0$. (ii) A function $f$ from $\Omega$ to a Borel space $(\mathcal{S}, \mathcal{F})$ is $\mathcal{A}^\mu$-measurable if and only if there is an $\mathcal{A}$-measurable map $g : \Omega \to (\mathcal{S}, \mathcal{F})$ such that $\mu$-a.e., $f = g$.

**Proof.** (i) Let $\tilde{\mathcal{A}}^\mu$ denote the set of $A \subset \Omega$ such that the $A', A''$ in the statement exist. We need to show that $\tilde{\mathcal{A}}^\mu = \mathcal{A}^\mu$. Clearly, $\mathcal{A}, \mathcal{N}_\mu \subset \tilde{\mathcal{A}}^\mu \subset \mathcal{A}^\mu$. It suffices to show that $\tilde{\mathcal{A}}^\mu$ is a $\sigma$-algebra. We need to show that (a) if $A \in \tilde{\mathcal{A}}^\mu$, then $A^c \in \tilde{\mathcal{A}}^\mu$; and (b) if $A_1, A_2, \cdots \in \tilde{\mathcal{A}}^\mu$, then $\bigcup_n A_n \in \tilde{\mathcal{A}}^\mu$. For (a), note that if $A' \subset A \subset A''$ with $A', A'' \in \mathcal{A}$ and $\mu(A'' \setminus A') = 0$, then $(A')^c \subset A^c \subset (A'')^c$, and $\mu((A')^c \setminus (A'')^c) = 0$. For (b), note that if for each $n, A'_n \subset A \subset A''_n$, $A'_n, A''_n \in \mathcal{A}$ and $\mu(A''_n \setminus A'_n) = 0$, then $A' := \bigcup_n A'_n, A'' := \bigcup_n A''_n \in \mathcal{A}$ and satisfy that $A' \subset A \subset A''$ and $0 \leq \mu(A'' \setminus A') \leq \sum_n \mu(A''_n \setminus A'_n) = 0$.

(ii) If the $g$ exists, then there is $N \in \mathcal{A}$ with $\mu N = 0$ such that $f = g$ on $N^c$. For any $B \in \mathcal{S}$, we have

$$f^{-1} B = ((f^{-1} B) \setminus N) \cup ((f^{-1} B) \cap N) = ((g^{-1} B) \setminus N) \cup ((f^{-1} B) \cap N).$$
So \((g^{-1}B) \setminus N \subset f^{-1}B \subset (g^{-1}B) \cup N\). Since \((g^{-1}B) \setminus N, (g^{-1}B) \cup N \in \mathcal{A}\) and \(\mu N = 0\), by (i) \(f^{-1}B \in \mathcal{A}^\mu\). So \(f\) is \(\mathcal{A}^\mu\)-measurable.

Now suppose \(f\) is \(\mathcal{A}^\mu\)-measurable. Since \(S\) is a Borel subset of \([0,1]\), we may assume that it is a Borel subset of \([0,1]\). We first show that there is an \(\mathbb{R}\)-valued \(\mathcal{A}\)-measurable function \(g\) such that \(\mu\)-a.e., \(f = g\). If \(f = 1_A\) for some \(A \in \mathcal{A}^m\u\), then by (i), there exist \(A', A'' \in \mathcal{A}\) with \(A' \subset A \subset A''\). Then \(\mu\)-a.e., \(f = 1_{A'} := g\). The statement then extends to simple measurable functions by linearity. Now suppose \(f \geq 0\). There exists a sequence of \(\mathcal{A}^\mu\)-measurable simple functions \((f_n)\) such that \(0 \leq f_n \uparrow f\). For each \(n\), there exists an \(\mathcal{A}\)-measurable simple function \(g_n\) such that \(\mu\)-a.e. \(f_n = g_n\). The sequence \((g_n)\) may not be nonnegative or increasing. However, we may choose \(N_n \in \mathcal{A}\) such that \(\mu N_n = 0\) and \(f_n = g_n\) on \(N_n^c\). Let \(N = \bigcup_n N_n\). Then \(N \in \mathcal{A}\) and \(\mu N = 0\), and \(0 \leq g_n \uparrow f\) on \(N^c\). Let \(g = \lim g_n\) on \(N^c\) and \(= 0\) on \(N\). Then \(g\) is \(\mathcal{A}\)-measurable and \(\mu\)-a.e., \(f = g\). Finally, we may modify the value of \(g\) such that \(g\) takes values in \(S\), and still satisfies other properties that we want. Let \(N \in \mathcal{A}\) be such that \(\mu N = 0\) and \(f = g\) on \(N^c\). Then \(g \in S\) on \(N^c\) since \(f\) takes values in \(S\). So \(g^{-1}S \subset N^c\). We now choose \(s_0 \in S\), and define \(\tilde{g}\) such that \(\tilde{g} = g\) on \(g^{-1}S \in A\) and \(\tilde{g} = s_0\) on \((g^{-1}S)^c\). Then \(\tilde{g} : \Omega \to S\) is \(\mathcal{A}\)-measurable, and \(\mu\)-a.e., \(\tilde{g} = g\), so \(\mu\)-a.e., \(f = \tilde{g}\).

It is natural to extend \(\mu\) to the completion \(\mathcal{A}^\mu\) in the way such that if \(A' \subset A \subset A''\) with \(A', A'' \in \mathcal{A}\) and \(\mu(A'' \setminus A') = 0\), then \(\mu A = \mu A'\). The definition is consistent, and defines a measure on \((\Omega, \mathcal{A}^\mu)\).

**Exercise.** Prove the statements in the above paragraph.

We are going to construct product measures. Let \((S, \mathcal{S}, \mu)\) and \((T, \mathcal{T}, \nu)\) be two \(\sigma\)-finite measure spaces. We want the product measure \(\mu \times \nu\) to be a measure on \(\mathcal{S} \times \mathcal{T}\) that satisfies

\[
(\mu \times \nu)(A \times B) = \mu A \times \nu B, \quad \forall A \in \mathcal{S} \text{ and } B \in \mathcal{T}. \tag{1.14}
\]

We will also show that such measure is unique. The \(\mu \times \nu\) is called the product of \(\mu\) and \(\nu\).

**Lemma 1.26.** For any measurable function \(f : S \times T \to \mathbb{R}_+\), and any \(t \in T\), the function \(f(\cdot, t) : S \to \mathbb{R}_+\) is \(\mathcal{S}\)-measurable. If we integrate \(f(\cdot, t)\) against \(\mu\) and get \(\mu f(\cdot, t) \in \mathbb{R}_+\) for each \(t \in T\), then \(t \mapsto \mu f(\cdot, t)\) is \(\mathcal{T}\)-measurable.

**Proof.** First suppose \(\mu\) is finite. Let \(\mathcal{C}\) denote the set of \(C \in \mathcal{S} \times \mathcal{T}\) such that the lemma holds for \(f = 1_C\). Then \(\mathcal{C}\) contains the \(\pi\)-system \(\{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\}\). In fact, if \(f = 1_{A \times B}\), then for \(t \in B\), \(f(\cdot, t) = 1_A\), and for \(t \in B^c\), \(f(\cdot, t) \equiv 0\). In either case \(f(\cdot, t)\) is \(\mathcal{S}\)-measurable. Moreover, \(\mu f(\cdot, t) = \mu A 1_B(t)\) is \(\mathcal{T}\)-measurable. Using the linearity of integrals, we easily see that \(\mathcal{C}\) is a \(\lambda\)-system. By monotone class theorem, \(\mathcal{C} = \mathcal{S} \times \mathcal{T}\). Thus, the lemma holds for indicator functions. By linearity and monotone convergence, the statement extends to nonnegative measurable functions.

Now we do not assume that \(\mu\) is finite. Since it is \(\sigma\)-finite, we may express \(\mu = \sum_n \mu_n\), where each \(\mu_n\) is a finite measure. The measurability of each \(f(\cdot, t)\) does not rely on the finiteness of \(\mu\). Since \(t \mapsto \mu_n f(\cdot, t)\) is \(\mathcal{T}\)-measurable for each \(n\), the same is true for \(t \mapsto \mu f(\cdot, t) = \sum_n \mu_n f(\cdot, t)\). \(\square\)
We may prove (1.15) for such integral \( f \) whenever \( f \) is measurable, e.g., \( f \in L^1(\mathbb{R}) \). The procedure is valid for measurable \( f : S \times T \to \mathbb{R}^+ \). The meaning of the first double integral is similar.

**Proof.** By a monotone class argument involving partitions of \( S \) and \( T \) into finite measurable sets, it is easy to see that there exists at most one product measure.

By Lemma 1.26, we may define
\[
(\mu \times \nu)C = \int \mu(ds) \int 1_C(s,t)\nu(dt), \quad C \in \mathcal{S} \times \mathcal{T}.
\]
Then \( \mu \times \nu \) is clearly a measure that satisfies (1.14). By uniqueness and symmetry, we also have
\[
(\mu \times \nu)C = \int \nu(dt) \int 1_C(s,t)\mu(ds), \quad C \in \mathcal{S} \times \mathcal{T}.
\]
Thus, (1.15) holds for indicator functions. By linearity and monotone convergence, the statement extends to measurable \( \mathbb{R}^+ \)-valued functions.

If \( f : S \times T \to \mathbb{R} \) is integrable w.r.t. \( \mu \times \nu \), then \( (\mu \times \nu)|f| < \infty \). By (1.15),
\[
\int \nu(dt) \int |f(s,t)|\mu(ds) < \infty.
\]
So for \( \nu \)-a.e. \( t \in T \), \( \int |f(s,t)|\mu(ds) < \infty \), i.e., \( f(\cdot,t) \) is integrable w.r.t. \( \mu \). So we may define \( \int f(s,t)\mu(ds) \) (as a function of \( t \)) outside a \( \nu \)-null set. Since \( |\int f(s,t)\mu(ds)| \leq \int |f(s,t)|\mu(ds) \) whenever \( f(\cdot,t) \) is \( \mu \)-integrable, by (1.16), \( t \mapsto \int f(s,t)\mu(ds) \) is \( \nu \)-integrable. So the double integral \( \nu(dt) \int f(s,t)\mu(ds) \) is well defined. Similarly, \( \int \mu(ds) \int f(s,t)\nu(dt) \) is also well defined. We may prove (1.15) for such \( f \) by expressing \( f = f_+ - f_- \).

Note that the product measure \( \mu \times \nu \) is also a \( \sigma \)-finite measure, and we may then define \( (\mu \times \nu) \times \sigma \) for another \( \sigma \)-finite measures. If \( (S_k, \mathcal{S}_k, \mu_k), 1 \leq k \leq n \), are \( \sigma \)-finite measures spaces, then we may use induction to construct the product measure \( \mu_1 \times \cdots \times \mu_n \) on \( \mathcal{S}_1 \times \cdots \times \mathcal{S}_n \), which is the unique measure that satisfies
\[
(\mu_1 \times \cdots \times \mu_n)(A_1 \times \cdots \times A_n) = \prod_{k=1}^n \mu_k A_k, \quad \forall A_k \in \mathcal{S}_k, \quad 1 \leq k \leq n.
\]

In the case all \( \mu_k \) are the same \( \mu \), we write the product as \( \mu^n \). For the Lebesgue measure \( \lambda \) on \( \mathbb{R} \), its power \( \mu^n \) is called the Lebesgue measure on \( \mathbb{R}^n \).

We may define the product of infinitely many measures, but need to assume that they are all probability measures.
**Definition.** Let \((S_t, \mathcal{S}_t, \mu_t), t \in T\), be a family of probability spaces. A probability measure \(\mu\) on the product measurable space \((\prod_t S_t, \mathcal{S}, \mu)\) is called the product of \(\mu_t, t \in T\), denoted by \(\prod_t \mu_t\), if for any finite \(\Lambda \subset T\), and \(A_\Lambda \in \mathcal{S}_\Lambda, \lambda \in \Lambda\), we have
\[
\mu \left( \prod_{\lambda \in \Lambda} A_\lambda \times \prod_{t \in T \setminus \Lambda} S_t \right) = \prod_{\lambda \in \Lambda} \mu_\lambda A_\lambda.
\]

By a monotone argument, we see that the product measure in the definition is unique, if it exists. The existence of the infinite product measure (assuming \(S_t\) are Borel spaces) will be proved in the next chapter.

**Definition.** A measurable group is a group \(G\) endowed with a \(\sigma\)-algebra \(\mathcal{G}\) such that the group operations in \(G\) are measurable. This means

(i) the map \(g \mapsto g^{-1}\) from \(G\) to \(G\) is \(\mathcal{G}/\mathcal{G}\)-measurable;

(ii) the map \((f, g) \mapsto fg\) from \(G^2\) to \(G\) is \(\mathcal{G}^2/\mathcal{G}\)-measurable.

If \(G\) is a topological group, i.e., endowed with a topology such that the group operations are continuous, and has a countable basis, then it is a measurable group. We will mainly work with the Euclidean space \(\mathbb{R}^n\) as a measurable group.

**Definition.** For two \(\sigma\)-finite measures \(\mu\) and \(\nu\) on a measurable group \(G\), the convolution of \(\mu\) and \(\nu\), denoted by \(\mu \ast \nu\), is the pushforward of the product measure \(\mu \times \nu\) under the map \((f, g) \mapsto fg\).

The convolution \(\mu \ast \nu\) may not be \(\sigma\)-finite. If both \(\mu\) and \(\nu\) are finite, \(\mu \ast \nu\) is also finite. If \(\mu_1, \mu_2, \mu_3\) are finite measures, then the associative law holds: \((\mu_1 \ast \mu_2) \ast \mu_3 = \mu_1 \ast (\mu_2 \ast \mu_3)\). If \(G\) is Abelian, then the commutative law holds: \(\mu \ast \nu = \nu \ast \mu\).

**Definition.** A measure \(\mu\) on a measurable group \(G\) is said to be right- or left invariant if \(\mu \circ T_g^{-1} = \mu\) for any \(g \in G\), where \(T_g\) denotes the right or left shift \(x \mapsto xg\) or \(x \mapsto gx\). If \(G\) is Abelian, right-invariance and left-invariance are equivalent.

**Example.** The Lebesgue measure \(\lambda^n\) is an invariant measure on \(\mathbb{R}^n\), and any locally finite invariant measure on \(\mathbb{R}^n\) is a scalar product of \(\lambda^n\).

**Lemma 1.28.** Let \((G, +)\) be an Abelian measurable group with an invariant measure \(\lambda\). Suppose \(\mu\) and \(\nu\) are \(\sigma\)-finite measures on \(G\) with \(\lambda\)-densities \(f\) and \(g\). Then \(\mu \ast \nu\) has a \(\lambda\)-density \(f \ast g\) given by
\[
(f \ast g)(s) = \int f(s-t)g(t)\lambda(dt) = \int f(t)g(s-t)\lambda(dt), \quad s \in G.
\]

**Proof.** Let \(\pi : G \times G \to G\) be the map \((s, t) \mapsto s + t\). Let \(A \in \mathcal{G}\). Then \((s, t) \in \pi^{-1} A\) if and only if \(t \in A - s := \{x - s : x \in A\}\). So
\[
(\mu \ast \nu)A = (\mu \times \nu)(\pi^{-1} A) = \int \mu(ds) \int 1_{\pi^{-1} A}(s, t)\nu(dt)
\]
and only if

So we may assume that

\[ \| \lambda \| \]

(i) If

\[ \text{Proof.} \]

\[ x \]

Applying the inequality to \( x \)

\[ \text{Lemma 1.30} \]

\[ \| | \equiv \| \]

\[ \| \]

\[ \| \]

(ii) for all \( p > 0 \), \( \| f \|_p \) defined by \( 1.17 \) agrees with the convolution of \( f \) and \( g \).

We now define \( L^p \)-spaces for \( p > 0 \). Given a measure space \( (\Omega, \mathcal{A}, \mu) \) and \( p > 0 \), we write \( L^p = L^p(\Omega, \mathcal{A}, \mu) \) for the class of all measurable functions \( f : \Omega \to \mathbb{R} \) with

\[ \| f \|_p := (\mu|f|^p)^{1/p} < \infty. \]

In particular, \( L^1 \) is the space of all integrable functions. We have a scaling property \( \| cf \|_p = |c|\| f \|_p \) for any \( c \in \mathbb{R} \).

**Lemma 1.30** (Hölder inequality and norm inequality). For any measurable functions \( f \) and \( g \) on \( \Omega \),

(i) if \( p, q > 1 \) and \( 1 = p^{-1} + q^{-1} \), then \( \| fg \|_1 \leq \| f \|_p \| g \|_q \);

(ii) for all \( p > 0 \), \( \| f + g \|_{p}^{\lambda} \leq \| f \|_{p}^{\lambda} + \| g \|_{p}^{\lambda} \).

**Proof.** (i) If \( \| f \|_p \) or \( \| g \|_q \) equals 0, then the inequality is trivial because \( fg = 0 \) a.e. If \( \| f \|_p \) and \( \| g \|_q \) are both positive, and one of them is \( \infty \), the inequality is also trivial because the RHS is \( \infty \). So we may assume that \( \| f \|_p, \| g \|_q \in (0, \infty) \). By scaling we may assume that \( \| f \|_p = \| g \|_q = 1 \).

The relation \( p^{-1} + q^{-1} = 1 \) implies that \( (p - 1)(q - 1) = 1 \). So for \( x, y \geq 0 \), \( y = x^{p-1} \) if and only if \( x = y^{q-1} \). Consider two subsets of \( \mathbb{R}^2 \): \( A_1 = \{(x, y) : 0 \leq x \leq x_0, 0 \leq y \leq x^{p-1}\} \) and \( A_2 = \{(x, y) : 0 \leq y \leq y_0, 0 \leq x \leq y^{q-1}\} \). By Fubini theorem, \( \lambda^2 A_1 = \int_{0}^{x_0} x^{p-1} dx \) and \( \lambda^2 A_2 = \int_{0}^{y_0} y^{q-1} dy \). Suppose \( (x, y) \in [0, x_0] \times [0, y_0] \). If \( y \leq x^{p-1} \), then \( (x, y) \in A_1 \); if \( y \geq x^{p-1} \), then \( x \leq y^{q-1} \), and \( (x, y) \in A_2 \). So \( [0, x_0] \times [0, y_0] \subset A_1 \cup A_2 \). Thus,

\[ x_0 y_0 = \lambda^2 [0, x_0] \times [0, y_0] \leq \lambda^2 A_1 + \lambda^2 A_2 = \int_{0}^{x_0} x^{p-1} dx + \int_{0}^{y_0} y^{q-1} dy = x_0^p/p + y_0^q/q. \]

Applying the inequality to \( x_0 = |f| \) and \( y_0 = |g| \), we get

\[ \| fg \|_1 = \mu|f||g| \leq \mu(\| f \|^p/p + \| g \|^q/q) = 1/p + 1/q = 1 = \| f \|_p \| g \|_q. \]

(ii) If \( p \in (0, 1] \), the inequality follows from the inequality \( (x + y)^p \leq x^p + y^p \) for any \( x, y \geq 0 \) (because \( x \mapsto x^p \) is a concave function). Suppose \( p > 1 \). If \( \| f \|_p \) or \( \| g \|_p = \infty \), the inequality
trivially holds. Suppose \( \|f\|_p, \|g\|_q < \infty \). Since \( |f + g|^p \leq 2^p(|f| \vee |g|)^p \leq 2^p(|f|^p + |g|^p) \), we get \( \|f + g\|_p < \infty \). By applying (i) to \( q := \frac{p}{p-1} \), we get

\[
\|f + g\|_p^p = \int |f + g|^pd\mu \leq \int |f|^p + |f|^{p-1}d\mu + \int |g|^p + |g|^{p-1}d\mu \\
\leq \|f\|_p \|f + g\|_q^{p-1} + \|g\|_p \|f + g\|_q^{p-1}.
\]

Note that

\[
\|f + g\|_q^{p-1} = \left( \int |f + g|^{(p-1)q}d\mu \right)^{1/q} = \left( \int |f + g|^p d\mu \right)^{\frac{p-1}{p}} = \|f + g\|_p^{p-1}.
\]

So \( \|f + g\|_p^p \leq \|f + g\|_p^{p-1}(\|f\|_p + \|g\|_p) \), which implies (ii) because \( \|f + g\|_p < \infty \). \( \square \)

Since \( \|f\|_p = 0 \) if and only if a.e. \( f = 0 \). By the norm inequality, \( L^p \) becomes a metric space with distance \( \rho(f, g) = \|f - g\|_p^{p\wedge 1} \) if we identify functions that agree \( \mu \)-a.e. From now on, \( L^p \) will be a space of measurable functions with \( \|f\|_p < \infty \) modulys the “equal almost everywhere” equivalence. We say that \( f_n \to f \) in \( L^p \) if \( \|f_n - f\|_p \to 0 \). For \( p \geq 1 \), \( L^p \) is a normed space. We now show that \( L^p \) is complete for all \( p > 0 \). Then for \( p \geq 1 \), \( L^p \) is a Banach space.

**Lemma 1.31.** Let \((f_n)\) be a Cauchy sequence in \( L^p \), where \( p > 0 \), then for some \( f \in L^p \), \( \|f_n - f\|_p \to 0 \).

**Proof.** First choose a subsequence \((f_{n_k})\) with \( \sum_k \|f_{n_{k+1}} - f_{n_k}\|_p^{p\wedge 1} < \infty \). By Lemma 1.30 and monotone convergence, we get \( \sum_k \|f_{n_{k+1}} - f_{n_k}\|_p^{p\wedge 1} < \infty \), and so \( \sum_k |f_{n_{k+1}} - f_{n_k}| < \infty \) a.e. Hence \((f_{n_k})\) is Cauchy in \( \mathbb{R} \) a.e. So there is a measurable function \( f \) such that \( f_{n_k} \to f \) a.e. By Fatou’s lemma,

\[
\int |f_n - f|^p d\mu \leq \liminf_k \int |f_n - f_{n_k}|^p d\mu \leq \sup_{m \geq n} \int |f_n - f_m|^p d\mu \to 0, \quad n \to \infty.
\]

Thus, \( f \in L^p \) and \( \|f_n - f\|_p \to 0 \). \( \square \)

**Lemma 1.32.** For any \( p > 0 \), let \( f, f_1, f_2, \ldots \in L^p \) with \( f_n \to f \) a.e. Then \( f_n \to f \) in \( L^p \) if and only if \( \|f_n\|_p \to \|f\|_p \).

**Proof.** If \( f_n \to f \) in \( L^p \), by the norm inequality,

\[
\|f_n\|_p^{p\wedge 1} - \|f\|_p^{p\wedge 1} \leq \|f_n - f\|_p^{p\wedge 1} \to 0,
\]

and so \( \|f_n\|_p \to \|f\|_p \). If \( \|f_n\|_p \to \|f\|_p \), then we define

\[
g_n = 2^p(|f_n|^p + |f|^p), \quad g = 2^{p+1}|f|^p.
\]

We have \( g_n \to g \) a.e. and \( \mu g_n \to \mu g = 2^{p+1}\|f\|_p^p < \infty \). Since \( g_n \geq |f_n - f|^p \to 0 \), by dominated convergence theorem, \( \mu|f_n - f|^p \to 0 \), i.e., \( f_n \to f \) in \( L^p \). \( \square \)
Lemma 1.33. Given a metric space $(S, \rho)$ and a finite measure $\mu$ on $(S, \mathcal{B}(S))$, for any $p > 0$, the space $C_b(S, \mathbb{R})$ of bounded real valued continuous functions on $S$ is dense in $L^p(S, \mathcal{B}(S), \mu)$.

Proof. Since $\mu$ is finite, we have $C_b \subseteq L^p(\mu)$. We need to show that the closure $\overline{C_b}$ of $C_b$ in $L^p$ equals $L^p$. First, for every open set $G$, there is a sequence $(f_n)$ in $C_b$ such that $f_n \to 1_G$ pointwise. We may choose $f_n(s) = 1 \wedge n\rho(x, G^c)$. Since $0 \leq f_n \leq 1$, by dominated convergence theorem, $f_n \to 1_G$ in $L^p$. So $1_G \in \overline{C_b}$. By Lemma 1.16, for every $B \in \mathcal{B}(S)$, $1_B \in \overline{C_b}$. Since $\overline{C_b}$ is a linear space, it then contains all measurable simple functions. By monotone convergence, we see that $\overline{C_b}$ contains all nonnegative functions in $L^p$, and so equals $L^p$. \hfill $\Box$

Because of Hölder’s inequality, if $f, g \in L^2$, $fg$ is integrable, and

$$|\int fg d\mu| \leq \|f\|_2 \|g\|_2.$$  

So $L^2$ is a Hilbert space with inner product: $\langle f, g \rangle := \int fg d\mu$.

Another important space is $L^\infty(\mu)$: the space of bounded measurable functions modulo “equal almost everywhere” equivalence. It is a Banach space with the norm

$$\|f\|_\infty := \inf\{a \geq 0 : |f| \leq a \mu - \text{a.e.}\}.$$  

Theorem. Suppose $\mu$ is a $\sigma$-finite measure. Let $p \in [1, \infty)$. Let $q = \frac{p}{p-1}$ if $p > 1$; and $q = \infty$ if $p = 1$. Then every continuous linear function $T : L^p \to \mathbb{R}$ corresponds to a unique $g \in L^q$ such that for any $f \in L^p$, $T(f) = \int fg d\mu$. Conversely, every $g \in L^q$ determines a continuous linear function on $L^p$ defined by $f \mapsto \int fg d\mu$. Moreover, for any $g \in L^q$,

$$\sup_{f \in L^p \setminus \{0\}} \frac{|\int fg d\mu|}{\|f\|_p} = \|g\|_q.$$  

This means that $L^q$ can be identified as $(L^p)^*$, the dual of $L^p$.

Sketch of the proof. Let $T$ be given. Let $\{A_n\}$ be a partition of $\Omega$ such that $\mu A_n < \infty$ for every $n$. For each $n$, we may define a real measure $\nu_n$ on $A_n$ such that $\nu_n A = T(1_A)$ for $A \in \mathcal{A}$ and $A \subseteq A_n$. If $\mu A = 0$, then $1_A = 0$ a.e. and so $T(1_A) = 0$, which implies that $\nu_n A = 0$. So $\nu_n \ll A$. By Radon-Nikodym theorem, there is a measurable $g_n$ on $A_n$ such that $\nu_n A = \int_A g_n d\mu$. Define $g$ on $\Omega$ such that $g|A_n = g_n$ for each $n$. Then using Hölder inequality, one can check that such $g$ satisfies the properties. \hfill $\Box$

Exercise. Complete the above proof.

Fix a measurable space $(S, \mathcal{S})$. Let $\mathcal{M}(S)$ denote the spaces of $\sigma$-finite measures on $(S, \mathcal{S})$. For each $B \in \mathcal{S}$, we define a map $\pi_B : \mathcal{M} \to \mathbb{R}_+$ such that $\pi_B(\mu) = \mu B$. We endow $\mathcal{M}(S)$ with the $\sigma$-algebra generated by the mappings $\pi_B$ for $B \in \mathcal{S}$, i.e.,

$$\sigma(\pi_B^{-1}(B(\mathbb{R}_+)) : B \in \mathcal{S}).$$

Then $\mathcal{M}(S)$ becomes a measurable space. Let $\mathcal{P}(S)$ denote the space of all probability measures on $(S, \mathcal{S})$. Then $\mathcal{P}(S) = \pi_S^{-1}\{1\}$ is a measurable subset of $\mathcal{M}(S)$.
Lemma 1.35. For any measurable spaces \((S, \mathcal{S})\) and \((T, \mathcal{T})\), the product mapping \((\mu, \nu) \mapsto \mu \times \nu\) is measurable from \(\mathcal{P}(S) \times \mathcal{P}(T)\) to \(\mathcal{P}(S \times T)\).

Proof. It suffices to show that for any \(C \subseteq \mathcal{S} \times \mathcal{T}\), \(\pi_C(\mu \times \nu) = (\mu \times \nu)C\) from \(\mathcal{P}(S) \times \mathcal{P}(T)\) to \(\mathbb{R}\) is measurable. Let \(\mathcal{C}\) denote the class of all such \(C\). Then \(\mathcal{C}\) is a \(\lambda\)-system. On the other hand, it contains the \(\pi\)-system \(\{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\}\), which generates the \(\sigma\)-algebra \(\mathcal{S} \times \mathcal{T}\).

By monotone class theorem, \(\mathcal{C}\) equals \(\mathcal{S} \times \mathcal{T}\). \(\square\)

**Definition.** Given two measurable spaces \((S, \mathcal{S})\) and \((T, \mathcal{T})\), a mapping \(\mu : S \times \mathcal{T} \to [0, \infty]\) is called a (probability) kernel from \(S\) to \(T\) if for every \(s \in S\), \(\mu_s := \mu(s, \cdot)\) is a (probability) measure on \((T, \mathcal{T})\), and for every \(B \in \mathcal{T}\), \(s \mapsto \mu(s, B)\) is a measurable function on \((S, \mathcal{S})\).

A measure \(\mu\) on \(T\) can be viewed as a kernel: \(\mu_s = \mu\) for every \(s \in S\). In general, a kernel from \(S\) to \(T\) can be understood as a \(\mathcal{S}\)-measurable measure on \((T, \mathcal{T})\). For a nonnegative measurable function \(f : T \to \mathbb{R}\), we may define the integral \(\mu f = \int \mu(s, dt) f(t)\). The value is a function on \(S\).

Lemma 1.37. Let \(\mathcal{C}\) be a \(\pi\)-system in \(T\) with \(\sigma(\mathcal{C}) = \mathcal{T}\). Let \(\{\mu_s : s \in S\}\) be a family of probability measures on \((T, \mathcal{T})\). The following are equivalent.

(i) \(\mu(s, B) := \mu_s(B)\) is a probability kernel from \(S\) to \(T\);

(ii) the map \(s \mapsto \mu_s\) from \(S\) to \(\mathcal{P}(T)\) is measurable;

(iii) for any \(B \in \mathcal{C}\), \(s \mapsto \mu_s B\) from \(S\) to \([0, 1]\) is measurable.

Proof. The equivalence between (i) and (iii) follows from monotone class theorem since the set of \(B \in \mathcal{T}\) such that \(s \mapsto \mu_s B\) is measurable form a \(\lambda\)-system. The equivalence between (i) and (ii) is also straightforward because by the definition of the \(\sigma\)-algebra on \(\mathcal{P}(T)\), the map \(s \mapsto \mu_s\) is measurable if and only if for any \(B \in \mathcal{T}\), \(s \mapsto \mu_s B\) is measurable. \(\square\)

Lemma 1.38. Fix three measurable spaces \((S, \mathcal{S})\), \((T, \mathcal{T})\), and \((U, \mathcal{U})\). Let \(\mu\) be a probability kernel from \(S\) to \(T\), and \(\nu\) be a probability kernel from \(S \times T\) to \(U\). Let \(f : S \times T \to \mathbb{R}\) and \(g : S \times T \to U\) be measurable. Then

(i) \(\mu_s f(s, \cdot)\) is a measurable function of \(s \in S\);

(ii) \(\mu_s \circ (g(s, \cdot))^{-1}\) is a kernel from \(S\) to \(U\);

(iii) we may define a probability kernel \(\mu \otimes \nu\) from \(S\) to \(T \times U\) by

\[
(\mu \otimes \nu)(s, C) = \int \mu(s, dt) \int \nu(s, t, du) 1_C(t, u), \quad C \subseteq T \times U. \tag{1.18}
\]

Proof. (i) By Lemma 1.26, for every \(s \in S\), \(f(s, \cdot)\) is measurable. So \(\mu_s f(s, \cdot)\) is well defined. If \(f = 1_{A \times B}\) for \(A \in \mathcal{S}\) and \(B \in \mathcal{T}\), then \(\mu_s f(s, \cdot) = 1_A(s) \mu_s B\) is measurable in \(s\). This then extends to all indicator functions by a monotone class argument, and to arbitrary \(f\) by linearity.
and monotone convergence. (ii) For every $s \in S$, $\mu_s \circ (g(s, \cdot))^{-1}$ is a probability measure on $U$. For any $B \in \mathcal{U}$, $(\mu_s \circ (g(s, \cdot))^{-1})B = \mu_s(1_B \circ g(s, \cdot))$. Since $(s, t) \mapsto 1_B(t) \circ g(s, t)$ from $S \times T$ to $\mathbb{R}_+$ is measurable, applying (i) to the function $f(s, t) := 1_B(t) \circ g(s, t)$, we see that $s \mapsto(\mu_s \circ (g(s, \cdot))^{-1})B$ is measurable. (iii) Applying (i) to the function $f((s, t), u) := 1_C(t, u)$, we see that $\int \nu(s, t, du)1_C(t, u)$ is a measurable function of $(s, t) \in S \times T$. Applying (i) again to the function $f(s, t) := \int \nu(s, t, du)1_C(t, u)$, we see that the RHS of (1.18) is well defined and measurable in $s \in S$ for a fixed $C \in \mathcal{T} \times \mathcal{U}$. When $s$ is fixed, by monotone convergence, $(\mu \otimes \nu)(s, \cdot)$ is a measure on $S \times T$. Since $\mu(s, \cdot)$ and $\nu(s, t, \cdot)$ are both probability measures, we get $(\mu \otimes \nu)(s, T \times U) = 1$. So $\mu \otimes \nu$ is a probability kernel from $S$ to $T \times U$. 

Note that when $\mu$ and $\nu$ are probability measures, i.e., $\mu$ does not depend on $s$ and $\nu$ does not depend on $(s, t)$, then $\mu \otimes \nu$ is the product measure $\mu \times \nu$.

By linearity and monotone convergence, for any measurable $f : T \times U \to \mathbb{R}_+$,

$$(\mu \otimes \nu)_s f = \int \mu(s, dt) \int \nu(s, t, du)f(t, u).$$

We may simply write it as $(\mu \otimes \nu)f = \mu(\nu f)$.

Suppose we have kernels $\mu_k$ from $S_0 \times \cdots \times S_{k-1}$ to $S_k$, $k = 1, \ldots, n$. By iteration we may combine them into a kernel $\mu_1 \otimes \cdots \otimes \mu_n$ from $S_0$ to $S_1 \times \cdots \times S_n$, given by

$$(\mu_1 \otimes \cdots \otimes \mu_n)f = \mu_1(\mu_2(\cdots(\mu_n f) \cdots))$$

for any measurable $f : S_1 \times \cdots S_n \to \mathbb{R}_+$. In the context of Markov chains, $\mu_k$ is often a kernel from $S_{k-1}$ to $S_k$, $1 \leq k \leq n$, and we can get a kernel $\mu_1 \cdots \mu_n$ from $S_0$ to $S_n$ given by

$$(\mu_1 \cdots \mu_n)_s B = (\mu_1 \otimes \cdots \otimes \mu_n)_s(S_1 \times \cdots \times S_{n-1} \times B)$$

$$= \int \mu_1(s, ds_1) \int \mu_2(s_1, ds_2) \cdots \int \mu_{n-1}(s_{n-2}, ds_{n-1}) \mu_n(s_{n-1}, B), \ s \in S_0, \ B \in \mathcal{F}_n.$$

**Exercise**. Problems 1, 6, 7, 15, 19 in Exercises of Chapter 1.

## 2 Processes, Distributions, and Independence

We now begin the study of probability theory. Throughout, fix a probability space $(\Omega, \mathcal{A}, \mathbb{P})$. In the probability context, the sets $A \in \mathcal{A}$ are called events, and $\mathbb{P} A = \mathbb{P}(A)$ is called the probability of $A$. Given a sequence of events, we may be interested in the events

$$\limsup A_n = \bigcap_{n} \bigcup_{m \geq n} A_m, \quad \liminf A_n = \bigcup_{n} \bigcap_{m \geq n} A_m.$$

Since $\omega \in \limsup A_n$ if and only if there are infinitely many $n$ such that $\omega \in A_n$, we also call $\limsup A_n$ the event that $A_n$ happens infinitely often, and denote it as $\{A_n \text{ i.o.}\}$. Since $\omega \in \liminf A_n$ if and only if there is $N$ such that $\omega \in A_n$ for all $n > N$, we also call $\liminf A_n$
the event that $A_n$ happens ultimately, and denote it as $\{A_n \\text{ult.}\}$. By basic set theory, we get $\{A_n \text{ i.o.}\}^c = \{A_n^\text{ult.}\}$. We may understand $\{A_n \text{ i.o.}\}$ and $\{A_n \text{ ult.}\}$ from another perspective. We view every $\omega \in \Omega$ as a universe. The space $\Omega$ is a collection of parallel universes. For a universe $\omega$, we understand $A_n$ as something that we know whether it happens at the time $n$. If $\omega \in A_n$, then in the universe $\omega$, $A_n$ happens at the time $n$. Then $\{A_n \text{ i.o.}\}$ is the collection of universes in which $A_n$ happen infinitely many times; and $\{A_n \text{ ult.}\}$ is the collection of universes in which all $A_n$ happen for $n$ big enough.

By countably subadditivity of $\mathbb{P}$, for any $m \in \mathbb{N}$,
\[
\mathbb{P}\{A_n \text{ i.o.}\} \leq \mathbb{P}\left[ \bigcup_{n=m}^{\infty} A_n \right] \leq \sum_{n=m}^{\infty} \mathbb{P}A_n.
\]
If $\sum_n \mathbb{P}A_n < \infty$, then $\sum_{n=m}^{\infty} \mathbb{P}A_n \to 0$ as $m \to \infty$. So we get $\mathbb{P}\{A_n \text{ i.o.}\} = 0$. This is the easy part of the Borel-Cantelli lemma.

A measurable mapping $f$ from $\Omega$ to another measurable space $(S, \mathcal{S})$ is called a random element in $S$. It is called a random variable when $S = \mathbb{R}$, a random vector when $S = \mathbb{R}^n$, a random sequence when $S = \mathbb{R}^\infty$, a random or stochastic process when $S$ is a function space, and a random measure (kernel) when $S$ is a class of measures. The notation $\mathbb{P}$-almost everywhere will now be called almost surely (abbreviated as a.s.). Let $(S, \mathcal{S})$ be a measurable space and $T$ be an abstract index set. Let $U \subset S^T$. A mapping $X$ from $\Omega$ to $U$, which is $U \cap \mathcal{S}^T$-measurable, is called an $S$-valued (random) process on $T$ with paths in $U$. By Lemma 1.8, $X$ can be treated as a family of random elements $X_t$ in the state space $S$.

Given a random element $\zeta$ in $(S, \mathcal{S})$, the pushforward $\mathbb{P} \circ \zeta^{-1}$ is a probability measure on $(S, \mathcal{S})$, and is called the distribution or law of $\zeta$. We write it as $\text{Law}(\zeta)$. For two random elements $\zeta$ and $\eta$ in the same measurable space, the equality $\zeta \overset{d}{=} \eta$ means that $\text{Law}(\zeta) = \text{Law}(\eta)$.

If for every $t \in T$, $X_t$ is a random element in a measurable space $(S_t, \mathcal{S}_t)$. Then $X = (X_t : t \in T)$ is a random element in $(\prod_t S_t, \prod_t \mathcal{S}_t)$. For every finite subset $\Lambda \subset T$, the associated finite-dimensional distribution is given by
\[
\mu_\Lambda = \text{Law}(X_t : t \in \Lambda).
\]
For $\Lambda_1 \subset \Lambda_2 \subset T$, we use $\pi_{\Lambda_2, \Lambda_1}$ to denote the natural projection from $\prod_{t \in \Lambda_2} S_t$ to $\prod_{t \in \Lambda_1} S_t$, which is measurable. We omit $\Lambda_2$ when it is equal to $T$. Since $(X_t : t \in \Lambda) = \pi_\Lambda(X)$, the finite dimensional distribution $\mu_\Lambda$ is the pushforwards of the law of $X$ under $\pi_\Lambda$, i.e.,
\[
\mu_\Lambda = \text{Law}(X_t : t \in \Lambda) = (\pi_\Lambda)_* \text{Law}(X).
\]
Let $\mathcal{P}(T)$ to denote the class of all nonempty finite subset of $T$. Suppose $\Lambda_1 \subset \Lambda_2 \in \mathcal{P}(T)$. From $\pi_{\Lambda_1} = \pi_{\Lambda_2, \Lambda_1} \circ \pi_{\Lambda_2}$ we get
\[
\mu_{\Lambda_1} = (\pi_{\Lambda_2, \Lambda_1})_* \mu_{\Lambda_2}, \quad \Lambda_1 \subset \Lambda_2 \in \mathcal{P}(T).
\]
If we have a family of finite dimensional distributions $\mu_\Lambda, \Lambda \in \mathcal{P}(T)$, on $\prod_{t \in \Lambda} S_t$, and the consistency condition (2.1) holds for every pair $\Lambda_1 \subset \Lambda_2 \in \mathcal{P}(T)$, then we call $(\mu_\Lambda \Lambda)_{\Lambda \in \mathcal{P}(T)}$ a consistent family.
Theorem 5.16 (Kolmogorov extension theorem). Suppose each $S_t$, $t \in T$, is a Borel space. Then for any consistent family $(\mu_{\Lambda})_{\Lambda \in \mathcal{P}_s(T)}$, there exists a unique probability measure $\mu$ on $\prod_{t \in T} S_t$ such that for every $\Lambda \in \mathcal{P}_s(T)$, $\mu_{\Lambda} = (\pi_{\Lambda})_\ast \mu$.

Remark . One important application of Kolmogorov extension theorem is the existence of infinite product measure. Suppose $T$ is an infinite index set, and for each $t \in T$, $\mu_t$ is a probability measure on a Borel measurable space $(S_t, \mathcal{B}_t)$. We define the family

$$\mu_{\Lambda} = \prod_{t \in \Lambda} \mu_t, \quad \Lambda \in \mathcal{P}_s(T),$$

where $\mathcal{P}_s(T)$ is the class of nonempty subsets of $T$. We have known that the finite product measures are well defined. The consistency condition is easy to check. Since $S_t$ are all Borel spaces, by Kolmogorov extension theorem, there is a unique probability measure $\mu$ on $\prod_{t \in T} S_t$ such that $\mu_{\Lambda} = (\pi_{\Lambda})_\ast (\mu)$ for every $\Lambda \in \mathcal{P}_s(T)$. Such $\mu$ is the product $\prod_{t \in T} \mu_t$.

For a random variable $\zeta$, the expected value, expectation, or mean of $\zeta$ is defined as

$$\mathbb{E}[\zeta] = \int_\Omega \zeta \, d\mathbb{P} = \int_{\mathbb{R}} x \, \text{Law}(\zeta)$$

whenever either integral exists. The last equality follows from Lemma 1.22. By that lemma, we also note that for any random element $\zeta$ in a measurable space $S$ and a measurable map $f : S \to \mathbb{R}$,

$$\mathbb{E}[f(\zeta)] = \int_\Omega f(\zeta) \, d\mathbb{P} = \int_S f(s) \, d\text{Law}(\zeta) = \int_{\mathbb{R}} xd\text{Law}(f \circ \zeta),$$

if any integral exists. For a random variable $\zeta$ and an event $A$, we often write $\mathbb{E}[\zeta; A]$ for $\mathbb{E}[1_A \zeta] = \int_A \zeta \, d\mathbb{P}$.

Proof of Kolmogorov extension theorem. The uniqueness part follows from the monotone class theorem.

We now consider the existence part. First assume that $T = \mathbb{N}$. Every Borel space $S_t$ is Borel isomorphic to a Borel subset of $[0, 1]$. Since the theorem depends only on the $\sigma$-algebra structure of $S_t$, we may assume that each $S_t$ is a Borel subset of $[0, 1]$. Then each $\mu_{\Lambda}$ can be also viewed as a probability measure on $[0, 1]^\Lambda$.

The proof uses Carathéodory extension theorem. For each $n \in \mathbb{N}$, let $\mathcal{F}_n$ denote the $\sigma$-algebra on $\prod_{k \in \mathbb{N}} S_{\kappa}$ generated by the projection $\pi_{\mathbb{N}_n}$, where $\mathbb{N}_n = \{1, \ldots, n\}$. This means that $\mathcal{F}_n$ is the family of subsets $A \subset [0, 1]^\mathbb{N}$ of the form $B \times [0, 1]^\mathbb{N}$, where $B \in \mathcal{B}([0, 1])^n$. Then $\mathcal{F}_n$ is increasing in $n$. Let $\mathcal{R} = \bigcup_n \mathcal{F}_n$. Then $\mathcal{R}$ is a ring in $[0, 1]^\mathbb{N}$, and $\mathcal{B}([0, 1])^\mathbb{N} = \sigma(\mathcal{R})$. We define $\mu : \mathcal{R} \to [0, 1]$ such that if $A = B \times [0, 1]^\mathbb{N} \in \mathcal{F}_n$ for some $B \in \mathcal{B}([0, 1])^n$, then $\mu A = \mu_{\mathbb{N}_n} B$. Such $\mu$ is well defined thanks to the consistency condition.

We now show that $\mu$ is a pre-measure. It is easy to see that $\mu$ satisfies the finitely additivity. It remains to show that if $A_1 \supset A_2 \supset \cdots \in \mathcal{R}$ with $\mu A_n \geq \varepsilon > 0$ for all $n$, then $\bigcap_n A_n \neq \emptyset$. Assume that $A_k \in \mathcal{F}_{n_k}$. Since $\mathcal{F}_n$ is increasing in $n$, we may assume that $(n_k)$ is increasing.
Let $\mu$ be a probability measure on $[0,1]$. For the existence of infinite product measure, we do not need to assume that $\mu$ of $A = \bigcup_{\text{finite}} \subset \Gamma$ is what we need. We now know that the theorem holds if $A = \bigcup_{\text{finite}} \subset \Gamma$ implies that $\muA = \bigcup_{\text{finite}} \subset \Gamma$, which together with $\mu\Lambda > \varepsilon$ implies that $\Lambda' = \bigcup_{\text{finite}} \subset \Gamma$ is compact, and each $A''_n$ is compact. The latter implies that $\mu(A_n \setminus \Lambda') \leq \sum_{j=1}^n \frac{\varepsilon}{2^j} < \varepsilon$, which together with $\mu\Lambda > \varepsilon$ implies that $\Lambda' \neq \emptyset$. Since $\Lambda' \supset \Lambda''_2 \supset \cdots$ and each $A''_n$ is compact, we get $\bigcap_n A''_n \neq \emptyset$, which together with $\Lambda''_n \subset A_n$implies that $\bigcap_n A_n \neq \emptyset$.

Thus, $\mu$ is a pre-measure on $\mathcal{R}$. By Carathéodory extension theorem, $\mu$ extends to a probability measure on $[0,1]$. By the definition of $\mu$ on $\mathcal{R}$, for every $n \in \mathbb{N}$, $\mu(\prod_{j=1}^n S_j \times [0,1]) = \mu_n \prod_{j=1}^n S_j = 1$. So $\mu \prod_{n=1}^\infty S_n = \lim_n \mu(\prod_{j=1}^n S_j \times [0,1]) = 1$. Thus, $\mu$ is also a probability measure on $\prod_{n=1}^\infty S_n$. For every $A_n \in \prod_{j=1}^\infty S_j \in \mathcal{B}([0,1])$, we have $\mu(A_n \times [0,1]) = \mu(A_n \times \prod_{j=n+1}^\infty S_j) = \mu(A_n \times [0,1]) = \mu_n(A_n)$. So $\mu_n = (\pi_{\mathcal{L}})_*(\mu')$ for every $n \in \mathbb{N}$. For every $\Lambda \in \mathcal{P}_s(\mathcal{N})$, there is $n \in \mathbb{N}$ such that $\Lambda \subset \mathcal{N}_n$. By (2.1) we have

$$\mu_\Lambda = (\pi_{\mathcal{L}})_*(\mu_n) = (\pi_{\mathcal{L}})_* \circ (\pi_{\mathcal{L}})_*(\mu) = (\pi_\Lambda)_*(\mu).$$

So $\mu$ is what we need. We now know that the theorem holds if $T$ is countable.

Finally, we consider a general $T$. Let $\mathcal{P}_s(T)$ denote the class of all nonempty countable subsets of $T$. We have proved that for any $\Gamma \in \mathcal{P}_s(T)$, there exists a unique probability measure $\mu_\Gamma$ on $\prod_{\text{finite}} S_\ell$ such that for any finite subset $\Lambda$ of $\Gamma$, $\mu_\Lambda = (\pi_{\mathcal{L}})_*(\mu_\Gamma)$. By the uniqueness, if $\Gamma_1 \subset \Gamma_2 \in \mathcal{P}_s(T)$, then $\mu_{\Gamma_1} = (\pi_{\mathcal{L}})_*(\mu_{\Gamma_2})$. For each $\Gamma \in \mathcal{P}_s(T)$, let

$$\mathcal{F}_\Gamma = (\pi_\Gamma)^{-1} \prod_{\text{finite}} S_\ell = \prod_{\text{finite}} S_\ell \times \prod_{\ell \notin \Gamma} S_\ell.$$ 

It is easy to check that $\bigcup_{\Gamma \in \mathcal{P}_s(T)} \mathcal{F}_\Gamma$ is a $\sigma$-algebra, and so equals $\prod_{\ell \in T} S_\ell$. We define $\mu : \bigcup_{\Gamma \in \mathcal{P}_s(T)} \mathcal{F}_\Gamma \to [0,1]$ such that if $A$ has an expression $\pi_\Gamma^{-1} B \in \mathcal{F}_\Gamma$ for some $\Gamma \in \mathcal{P}_s(T)$ and $B \in \prod_{\ell \in \Gamma} S_\ell$, then $\mu A = \mu_\Gamma B$. The value of $\mu A$ does not depend on the choice of the expression of $A$ thanks to the consistency condition $\mu_{\Gamma_1} = (\pi_{\mathcal{L}})_*(\mu_{\Gamma_2})$. So $\mu$ is well defined. From the definition, $\mu = (\pi_\Gamma)_* \mu$ for every $\Gamma \in \mathcal{P}_s(T)$. If $\Lambda \in \mathcal{P}_s(T)$, we may pick $\Gamma \in \mathcal{P}_s(T)$ with $\Gamma \supset \Lambda$. Then we get the desired equality $\mu_\Lambda = (\pi_{\mathcal{L}})_*(\mu) = (\pi_\Lambda)_* \mu$. 

Remark. For the existence of infinite product measure, we do not need to assume that the $S_\ell$ are Borel spaces. The proof still uses Carathéodory extension theorem. Following the proof of Kolmogorov extension theorem and the construction of the infinite product measure, we need to show that, if $T = \mathbb{N}$, and $A_1 \supset A_2 \supset \cdots$ satisfy that for some $\varepsilon > 0$,

$$A_n = B_n \times \prod_{j>n} S_j,$$

for some $B_n \in \prod_{j=1}^n S_j$ with $(\prod_{j=1}^n \mu_j) B_n \geq \varepsilon$, for all $n \in \mathbb{N}$, then $\bigcap_n A_n \neq \emptyset$. 

31
For $n > m \in \mathbb{N}$ and $(x_1, \ldots, x_m) \in \prod_{j=1}^{m} S_j$, we define

$$B_n(x_1, \ldots, x_m) = \{(x_{m+1}, \ldots, x_n) \in \prod_{j=m+1}^{n} S_j : (x_1, x_2, \ldots, x_n) \in B_n\}.$$

By Lemma 1.26, for each $(x_1, \ldots, x_m) \in \prod_{j=1}^{m} S_j$, $B_n(x_1, \ldots, x_m)$ is a measurable subset of $\prod_{j=m+1}^{n} S_j$, and $(x_1, \ldots, x_m) \mapsto (\prod_{j=m+1}^{n} \mu_j)B_n(x_1, \ldots, x_m)$ is a measurable function on $\prod_{j=1}^{m} S_j$. For $n \geq 2$, let

$$F_{n}^{(1)} = \{x_1 \in S_1 : (\prod_{j=2}^{n} \mu_j)B_n(x_1) > \varepsilon/2\}.$$

Then $F_2^{(1)} \supset F_3^{(1)} \supset \cdots$ are measurable subsets of $S_1$. By Fubini theorem,

$$\varepsilon \leq (\prod_{j=1}^{n} \mu_j)B_n = \int \mu_1(dx_1)(\prod_{j=2}^{n} \mu_j)B_n(x_1) \leq \frac{\varepsilon}{2}(\prod_{j=1}^{n} \mu_j)^c + \mu_1F_{n}^{(1)}$$

which implies that $\mu_1F_{n}^{(1)} \geq \varepsilon/2$ for all $n \geq 2$. So $\mu_1 \cap_{n} F_{n}^{(1)} \geq \varepsilon/2$, and then we have $\cap_{n \geq 2} F_{n}^{(1)} \neq \emptyset$.

Pick $x_1 \in \cap_{n \geq 2} F_{n}^{(1)}$. Let $B_{n}^{(1)} = B_n(x_1)$, $n \geq 2$. For every $n \geq 3$, and $x_2 \in S_2$, let

$$B_{n}^{(1)}(x_2) = B_{n}(x_1, x_2) = \{(x_3, \ldots, x_n) \in \prod_{j=3}^{n} S_j : (x_1, x_2, x_3, \ldots, x_n) \in B_n\}.$$

For $n \geq 3$, let

$$F_{n}^{(2)} = \{x_2 \in S_2 : (\prod_{j=3}^{n} \mu_j)B_{n}^{(1)}(x_2) > \varepsilon/4\}.$$

Using Fubini theorem and a similar argument as above, we get $\cap_{n \geq 3} F_{n}^{(2)} \neq \emptyset$. So we may pick $x_2 \in \cap_{n \geq 3} F_{n}^{(2)}$. Then $(\prod_{j=3}^{n} \mu_j)B_n(x_1, x_2) > \varepsilon/4$ for any $n \geq 3$.

Repeating the argument, we can find a sequence $x := (x_1, x_2, \ldots) \in \prod_{k} S_k$ such that $x_k \in S_k$, $k \in \mathbb{N}$, and

$$\left(\prod_{j=m+1}^{n} \mu_j\right)B_n(x_1, \ldots, x_n) > \varepsilon/2^n, \quad \forall m > n \in \mathbb{N}.$$

We now show that $x \in \cap_{n} A_n$. Pick any $n \in \mathbb{N}$, since $A_n = B_n \times \prod_{j=n+1}^{\infty} S_j$, to prove that $x \in A_n$, it suffices to show that $(x_1, \ldots, x_n) \in B_n$. To prove this assertion, note that from $\mu_{n+1}B_{n+1}(x_1, \ldots, x_n) > 0$ we get $B_{n+1}(x_1, \ldots, x_n) \neq \emptyset$. So there is $x_{n+1} \in S_{n+1}$ such that $(x_1, \ldots, x_n, x_{n+1}) \in B_{n+1}$. From $A_{n+1} \subset A_n$, we get $B_{n+1} \subset B_n \times S_{n+1}$, which then implies $(x_1, \ldots, x_n) \in B_n$. 

32
A random vector \( \zeta \) in \( \mathbb{R}^n \) is called integrable if every component \( \zeta_j \), \( 1 \leq j \leq n \), is integrable.

**Lemma 2.5** (Jensen’s inequality). Let \( \zeta \) be an integrable random vector in \( \mathbb{R}^n \). Let \( f : \mathbb{R}^n \to \mathbb{R}_+ \) be convex, i.e.,

\[
f(px + (1-p)y) \leq pf(x) + (1-p)f(y), \quad x, y \in \mathbb{R}^n, \quad 0 \leq p \leq 1.
\]

Then \( f(\mathbb{E}\zeta) \leq \mathbb{E}[f(\zeta)] \).

**Proof.** We use a version of Hahn-Banach Theorem, which asserts that

\[
f(x) = \sup_L L(x),
\]

where the supremum is over all affine functions \( L : \mathbb{R}^n \to \mathbb{R} \) with \( L \leq f \). Since for every affine function \( L \leq f \),

\[
L(\mathbb{E}\zeta) = \mathbb{E}[L(\zeta)] \leq \mathbb{E}[f(\zeta)],
\]

taking the supremum over all affine functions \( L \leq f \), we get \( f(\mathbb{E}\zeta) \leq \mathbb{E}[f(\zeta)] \). \( \square \)

For a random variable \( \zeta \) and \( p > 0 \), the integral \( \mathbb{E}|\zeta|^p = \|\zeta\|_p^p \) is called the \( p \)-th absolute moment of \( \zeta \).

**Lemma 2.4.** For any random variable \( \zeta \geq 0 \) and \( p > 0 \),

\[
\mathbb{E}\zeta^p = \int_0^\infty \mathbb{P}\{\zeta > t\} t^{p-1} dt = p \int_0^\infty \mathbb{P}\{\zeta > t\} t^{p-1} dt.
\]

**Proof.** By Fubini’s theorem and change of variables,

\[
\mathbb{E}\zeta^p = \int_0^\infty \mathbb{E}\{1\{\zeta^p > s\}\} ds = \int_0^\infty \mathbb{E}1\{\zeta > s^{1/p}\} ds
\]
\[
= \int_0^\infty \mathbb{E}1\{\zeta > t\} pt^{p-1} dt = p \int_0^\infty \mathbb{P}\{\zeta > t\} t^{p-1} dt.
\]

Here in the third “=” we used \( s = tp \). The proof if the second expression is similar. \( \square \)

**Exercise.** Show that \( \|\zeta\|_p \leq \|\zeta\|_q \) if \( p \leq q \). Here we use the fact that \( \mathbb{P}\Omega = 1 \). So the \( L^p \)-spaces are decreasing in \( p \).

The **covariance** of two random variables \( \zeta, \eta \in L^2 \) is given by

\[
\text{cov}(\zeta, \eta) = \mathbb{E}(\zeta - \mathbb{E}\zeta)(\eta - \mathbb{E}\eta) = \mathbb{E}\zeta\eta - \mathbb{E}\zeta\mathbb{E}\eta.
\]

It is clearly bilinear. The **variance** of \( \zeta \in L^2 \) is defined by

\[
\text{var}(\zeta) = \text{cov}(\zeta, \zeta) = \mathbb{E}(\zeta - \mathbb{E}\zeta)^2 = \mathbb{E}\zeta^2 - (\mathbb{E}\zeta)^2.
\]
By Cauchy inequality, \[ |\text{cov}(\zeta, \eta)|^2 \leq \text{var}(\zeta)\text{var}(\eta). \]

We say that \( \zeta \) and \( \eta \) are \textit{uncorrelated} if \( \text{cov}(\zeta, \eta) = 0 \).

For any collection \( \zeta \in L^2, t \in T \), the associated \textit{covariance function} \( \rho_{s,t} = \text{cov}(\zeta_s, \zeta_t), s, t \in T \), is \textit{nonnegative definite}, in the sense that for any \( n \in \mathbb{N}, t_1, \ldots, t_n \in T \), and \( a_1, \ldots, a_n \in \mathbb{R} \), \( \sum_{i,j} a_i a_j \rho_{t_i, t_j} \geq 0 \). This is because

\[
\sum_{i,j} a_i a_j \rho_{t_i, t_j} = \sum_{i,j} a_i a_j E(\zeta_{t_i} - E\zeta_{t_i})(\zeta_{t_j} - E\zeta_{t_j}) = E(\sum_i a_i (\zeta_{t_i} - E\zeta_{t_i}))^2 \geq 0.
\]

\textbf{Example}. We now study the following distributions (i.e. probability measures) on \( \mathbb{R} \). In each case below, we suppose \( \zeta \) is a random variable with \( \text{Law}(\zeta) = \mu \). Recall that \( E\zeta = \int xd\mu \) and \( \text{var}(\zeta) = E\zeta^2 - (E\zeta)^2 = \int x^2 d\mu - (\int xd\mu)^2 \) are determined by \( \mu \). We first consider discrete distributions, which are combinations of Dirac measures.

(i) The degenerate distribution at \( x_0 \). This is the point mass \( \mu = \delta_{x_0}, x_0 \in \mathbb{R} \). We have \( E\zeta = \int xd\delta_{x_0} = x_0 \) and \( E\zeta^2 = \int x^2 d\delta_{x_0} = x_0^2 \) and so \( \text{var}(\zeta) = 0 \).

(ii) The Bernoulli distribution with parameter \( p \in [0,1] \). The measure, denoted by \( B(p) \), has the form \( \mu = p\delta_1 + (1-p)\delta_0 \). We have \( E\zeta = p(1) + (1-p)(0) = p \) and \( E\zeta^2 = p(1^2) + (1-p)(0^2) = p \). So \( \text{var}(\zeta) = p - p^2 \).

(iii) The binomial distribution with parameter \( n \in \mathbb{N} \) and \( p \in [0,1] \). The measure, denoted by \( B(n,p) \), has the form \( \mu = \sum_{k=0}^{n} p^k(1-p)^{n-k}\binom{n}{k}\delta_k \). It is a probability measure because \( \sum_{k=0}^{n} p^k(1-p)^{n-k}\binom{n}{k} = (p + (1-p))^n = 1 \). We have

\[
E\zeta = \sum_{k=0}^{n} p^k(1-p)^{n-k}\binom{n}{k} = \sum_{k=1}^{n} p^k(1-p)^{n-k}\frac{n!}{(k-1)!(n-k)!} = np;
\]

\[
E(\zeta^2 - \zeta) = \sum_{k=0}^{n} p^k(1-p)^{n-k}k\binom{n}{k} = n(n-1)p^2 \sum_{k=2}^{n} p^{k-2}(1-p)^{n-k}\frac{(n-2)!}{(k-1)!(n-k)!} = n(n-1)p^2.
\]

So \( \text{var}(\zeta) = E(\zeta^2 - \zeta) + E\zeta - (E\zeta)^2 = np - p^2 \).
(iv) The geometric distribution with parameter \( p \in (0, 1) \). The measure, denoted by \( \text{Geom}(p) \), has the form \( \mu = \sum_{k=1}^{\infty} (1 - p)^{k-1} p \delta_k \). It is a probability measure because \( \sum_{k=1}^{\infty} (1 - p)^{k-1} p = \frac{p}{1 - (1 - p)} = 1 \), where we used \( \sum_{k=0}^{\infty} x^k = \frac{1}{1-x} \) for \( |x| < 1 \). We have

\[
\mathbb{E} \zeta = \sum_{k=1}^{\infty} k(1 - p)^{k-1} p = \frac{p}{(1 - (1 - p))^2} = \frac{1}{p};
\]

\[
\mathbb{E}(\zeta^2 - \zeta) = \sum_{k=1}^{\infty} k(k - 1)(1 - p)^{k-2} p = \frac{2p(1 - p)}{(1 - (1 - p))^3} = \frac{2(1 - p)}{p^2}.
\]

Here we used the equalities \( \sum_{k=1}^{\infty} k x^{k-1} = \frac{1}{(1-x)^2} \) and \( \sum_{k=2}^{\infty} k(k - 1)x^{k-2} = \frac{2}{(1-x)^3} \) for \( |x| < 1 \), which can be proved by differentiating the equality \( \sum_{k=0}^{\infty} x^k = \frac{1}{1-x} \). Thus, \( \text{var}(\zeta) = \mathbb{E}(\zeta^2 - \zeta) + \mathbb{E} \zeta - (\mathbb{E} \zeta)^2 = \frac{2(1 - p)}{p^2} + \frac{1}{p} - \frac{1}{p^2} = \frac{1}{p^2} \).

(v) The Poisson distribution with parameter \( \lambda > 0 \). The measure, denoted by \( \text{Pois}(\lambda) \), has the form \( \mu = \sum_{k=0}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} \delta_k \). It is a probability measure because \( \sum_{k=0}^{\infty} \frac{\lambda^k}{k!} = e^\lambda \). We have

\[
\mathbb{E} \zeta = \sum_{k=0}^{\infty} \frac{k \lambda^k}{k!} = \lambda \sum_{k=1}^{\infty} \frac{\lambda^{k-1}}{(k-1)!} = \lambda;
\]

\[
\mathbb{E}(\zeta^2 - \zeta) = \sum_{k=0}^{\infty} k(k - 1) \frac{\lambda^k}{k!} = \lambda^2 \sum_{k=2}^{\infty} \frac{\lambda^{k-2}}{(k-2)!} = \lambda^2.
\]

So \( \text{var}(\zeta) = \mathbb{E}(\zeta^2 - \zeta) + \mathbb{E} \zeta - (\mathbb{E} \zeta)^2 = \lambda^2 + \lambda - \lambda^2 = \lambda \).

Below are continuous distributions on \( \mathbb{R} \), which have density functions w.r.t. the Lebesgue measure \( \lambda \). In each example below, \( f \) is the \( \lambda \)-density of \( \text{Law}(\zeta) \). Then \( \mathbb{E} \zeta = \int_{\mathbb{R}} x f(x) dx \) and \( \mathbb{E} \zeta^2 = \int_{\mathbb{R}} x^2 f(x) dx \).

(i) The uniform distribution \( U[a, b] \) for \( a < b \in \mathbb{R} \). The density is \( f(x) = \frac{1}{b-a} 1_{[a,b]} \). Then

\[
\mathbb{E} \zeta = \frac{1}{b-a} \int_a^b x dx = \frac{1}{b-a} \frac{x^2}{2} \bigg|_a^b = \frac{a+b}{2} \quad \text{and} \quad \mathbb{E} \zeta^2 = \frac{1}{b-a} \int_a^b x^2 dx = \frac{1}{b-a} \frac{x^3}{3} \bigg|_a^b = \frac{1}{3} (a^2 + ab + b^2).
\]

So \( \text{var}(\zeta) = \frac{1}{3} (a^2 + ab + b^2) - (\frac{a+b}{2})^2 = \frac{(a-b)^2}{12} \).

(ii) The exponential distribution \( \text{Exp}(\lambda) \) with parameter \( \lambda > 0 \). The density is \( 1_{[0,\infty)} \lambda e^{-\lambda x} \).

It is a probability measure because \( \int_0^\infty \lambda e^{-\lambda x} dx = 1 \). We have

\[
\mathbb{E} \zeta = \int_0^\infty x \lambda e^{-\lambda x} dx = -\int_0^\infty (-e^{-\lambda x}) dx = \frac{1}{\lambda};
\]

\[
\mathbb{E} \zeta^2 = \int_0^\infty x^2 \lambda e^{-\lambda x} dx = -\int_0^\infty 2x(-e^{-\lambda x}) dx = \frac{2}{\lambda^2}.
\]

Here we use integration by parts. So \( \text{var}(\zeta) = \mathbb{E} \zeta^2 - (\mathbb{E} \zeta)^2 = \frac{1}{\lambda^2} \).
(iii) The normal distribution $N(\mu, \sigma^2)$ with parameter $\mu \in \mathbb{R}$ and $\sigma > 0$. The density is

$$f(x) = \frac{1}{\sqrt{2\pi \sigma}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$ 

It is a probability measure because using a change of variable $x = \mu + \sqrt{\sigma}y$, we get

$$\frac{1}{\sqrt{2\pi \sigma}} \int_{\mathbb{R}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} dx = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-y^2/2} dy,$$

and by Fubini’s theorem and using polar coordinate,

$$\left( \int_{\mathbb{R}} e^{-y^2/2} dy \right)^2 = \int_{\mathbb{R}} \int_{\mathbb{R}} e^{-x^2/2} e^{-y^2/2} dxdy = \int_{0}^{2\pi} \int_{0}^{\infty} e^{-r^2/2} rdrd\theta$$

$$= 2\pi \int_{0}^{\infty} e^{-r^2/2} rdr = 2\pi (-e^{-r^2/2})|_{0}^{\infty} = 2\pi.$$

Using the same change of variable $x = \mu + \sigma y$, we get

$$\mathbb{E}[\zeta] = \frac{1}{\sqrt{2\pi \sigma}} \int_{\mathbb{R}} xe^{-\frac{(x-\mu)^2}{2\sigma^2}} dx = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} (\mu + \sigma y)e^{-y^2/2} dy = \mu;$$

$$\mathbb{E}[\zeta^2] = \frac{1}{\sqrt{2\pi \sigma}} \int_{\mathbb{R}} x^2 e^{-\frac{(x-\mu)^2}{2\sigma^2}} dx = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} (\mu + \sigma y)^2 e^{-y^2/2} dy$$

$$= \mu + \sigma^2 \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} y^2 e^{-y^2/2} dy.$$

Here we used that $\int_{\mathbb{R}} ye^{-y^2/2} dy = 0$ because the integrand is odd. Thus,

$$\text{var}(\zeta) = \sigma^2 \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} y^2 e^{-y^2/2} dy = \sigma^2 \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-y^2/2} dy = \sigma^2,$$

where we used integration by parts: differentiating $y$ and integrating $ye^{-y^2/2}$.

We understand the degenerate distribution $\delta_\mu$ as a normal distribution $N(\mu, 0)$, which does not have a $\lambda$-density. In this case it trivially holds that $\mathbb{E}[\zeta] = \mu$ and $\text{var}(\zeta) = 0$. If $\text{Law}(\zeta) = N(\mu, \sigma^2)$, then for any $a, b \in \mathbb{R}$, $\text{Law}(a\zeta + b) = N(a\mu + b, a^2\sigma^2)$.

**Exercise**. Prove the following

(i) The binomial distribution $B(n, p)$ is the $n$-th convolution power of the Bernoulli distribution $B(p)$, i.e.,

$$B(p) \ast \cdots \ast B(p) = B(n, p).$$
(ii) The Poisson distributions satisfy that for any \( \lambda_1, \lambda_2 > 0 \),
\[
Pois(\lambda_1) * Pois(\lambda_2) = Pois(\lambda_1 + \lambda_2).
\]

(iii) The normal distributions satisfy that for any \( \mu_1, \mu_2 \in \mathbb{R} \) and \( v_1, v_2 \geq 0 \),
\[
N(\mu_1, v_1) * N(\mu_2, v_2) = N(\mu_1 + \mu_2, v_1 + v_2).
\]

**Example.** There exists a probability measure on \( \mathbb{R} \), which is not a combination of a discrete distribution and a continuous distribution. Consider the Cantor \( \frac{1}{3} \) set:
\[
C = \left\{ \sum_{n=1}^{\infty} \frac{a_n}{3^n} : a_n \in \{0, 2\}, n \in \mathbb{N} \right\}.
\]
It is Borel isomorphic to the product space \( \{0, 2\}^\infty \). Let \( f : \{0, 2\}^\infty \to C \) be the bijective measurable map
\[
f((a_n)_{n \in \mathbb{N}}) = \sum_{n=1}^{\infty} \frac{a_n}{3^n}.
\]
Let \( \mu = \frac{1}{2}(\delta_0 + \delta_2) \) be a probability measure on \( \{0, 2\} \). We have known that the product measure \( \mu^\infty \) exists on \( \{0, 2\}^\infty \). The pushforward measure \( f_* \mu^\infty \) is a probability measure on \( C \). Then \( f_* \mu^\infty(C^c) = 0 \). We know that \( \lambda(C) = 0 \). So \( f_* \mu^\infty \perp \lambda \). We also see that \( f_* \mu^\infty \) has no point mass, i.e., there does not exist \( x \in C \) such that \( f_* \mu^\infty(\{x\}) > 0 \), because \( \mu^\infty \) has no point mass.

**Exercise.** Let \( \mu = \frac{1}{2}(\delta_0 + \delta_1) \) be a probability measure on \( \{0, 1\} \). Let \( f : \{0, 1\}^\infty \to [0, 1] \) be defined by
\[
f((a_n)_{n \in \mathbb{N}}) = \sum_{n=1}^{\infty} \frac{a_n}{2^n}.
\]
Prove that \( f \) is measurable, and \( f_* \mu^\infty = \lambda(\cdot \cap [0, 1]) \).

We now define and study the notation of independence. The events \( A_t, t \in T \), are said to be *(mutually) independent* (w.r.t. \( \mathbb{P} \)) if for any distinct indices \( t_1, \ldots, t_n \in T \),
\[
\mathbb{P}\left[ \bigcap_{k=1}^{n} A_{t_k} \right] = \prod_{k=1}^{n} \mathbb{P} A_{t_k}. \tag{2.2}
\]
We say that a class of families \( C_t, t \in T \), are independent, if when we pick an \( A_t \) in every \( C_t \), then \( A_t, t \in T \), are independent. We do not require the independence between events in the same family \( C_t \). The random elements \( \zeta_t, t \in T \), are said to be independent if the independence holds for the generated \( \sigma \)-algebras \( \sigma(\zeta_t), t \in T \).

**Lemma 2.10** *(Strengthened version).* For each \( t \in T \), let \( \zeta_t \) be a random element in a measurable space \( (S_t, \overline{S}_t) \). Let \( \zeta = (\zeta_t : t \in T) \) be a random element in \( \prod_{t \in T} S_t \). Then \( \zeta_t, t \in T \), are independent iff
\[
\text{Law}(\zeta) = \prod_{t \in T} \text{Law}(\zeta_t).
\]

37
Lemma 2.6. We have each $C_\tau$, $\tau \in T$, defined on it such that $\text{Law}(\zeta_\tau) = \mu_\tau$ for each $\tau$.

Proof. We have shown that the product measure $\prod_{t \in T} \mu_t$ on $(\prod_{t \in T} S_t, \prod_{t \in T} \mathcal{F}_t)$ exists. Let $(\Omega, \mathcal{A}, \mathbb{P}) = \left( \prod_{t \in T} S_t, \prod_{t \in T} \mathcal{F}_t, \prod_{t \in T} \mu_t \right)$. For each $t \in T$, let the random element $\zeta_t : \Omega \to S_t$ be the projection map $\pi_t$. Then the random element $\zeta = (\zeta_t : t \in T)$ from $\Omega$ to $\prod_{t \in T} S_t = \Omega$ is just the identity map. So $\text{Law}(\zeta_t) = (\pi_t) \cdot \prod_{s \in T} \mu_s = \mu_t$, $t \in T$, and $\text{Law}(\zeta) = \prod_{t \in T} \mu_t$. By Lemma 2.10, $\zeta_t$, $t \in T$, are independent.

Lemma 2.6. If the $\pi$-systems $\mathcal{C}_t$, $t \in T$, are independent, then so are the $\sigma$-fields $\mathcal{F}_t := \sigma(\mathcal{C}_t)$, $t \in T$.

Proof. We need to show that for any distinct indices $t_1, \ldots, t_n \in T$, and any $A_{t_k} \in \mathcal{F}_{t_k}$, $1 \leq k \leq n$, (2.2) holds. By assumption, it is true if $A_{t_k} \in \mathcal{C}_{t_k}$, $1 \leq k \leq n$. By a monotone class argument, we may first weaken the assumption on $A_{t_1}$ from $A_{t_1} \in \mathcal{C}_{t_1}$ to $A_{t_1} \in \mathcal{F}_{t_1}$, and then weaken the assumption on $A_{t_2}$ from $A_{t_2} \in \mathcal{C}_{t_2}$ to $A_{t_2} \in \mathcal{F}_{t_2}$. Repeating the argument until we weaken the assumptions of all $A_{t_k}$ from $A_{t_k} \in \mathcal{C}_{t_k}$ to $A_{t_k} \in \mathcal{F}_{t_k}$, then we get the desired equality.

Corollary 2.7. Let $\mathcal{F}_t$, $t \in T$, be independent $\sigma$-algebras. Let $R_s$, $s \in S$, be a partition of $T$. Then the $\sigma$-algebras $\mathcal{F}_s = \bigvee_{t \in R_s} \mathcal{F}_t := \sigma(\bigcup_{t \in R_s} \mathcal{F}_t)$, $s \in S$, are independent.

Proof. For each $s \in S$, let $\mathcal{C}_s$ denote the set of all finite intersections of sets in $\bigcup_{t \in R_s} \mathcal{F}_t$. Then each $\mathcal{C}_s$ is a $\pi$-system, and it is straightforward to check that $\mathcal{C}_s$, $s \in S$, are independent. By Lemma 2.6, we have $\mathcal{F}_s = \sigma(\mathcal{C}_s)$, $s \in S$, are independent.

Pairwise independence between two objects $A$ and $B$ will be denoted by $A \perp B$. In general, pairwise independence between all pairs of $A_t$, $t \in T$, say, does not imply the (total) independence of the group $A_t$, $t \in T$.

Lemma 2.8. The $\sigma$-algebras $\mathcal{F}_1, \mathcal{F}_2, \ldots$ are independent iff $\bigvee_{k \leq n} \mathcal{F}_k \perp \mathcal{F}_{n+1}$ for all $n$.

Proof. The “only if” part follows from Corollary 2.7. For the “if” part, it suffices to show that for any $n \in \mathbb{N}$ and $A_k \in \mathcal{F}_k$, $1 \leq k \leq n$, we have $\mathbb{P} \bigcap_{k=1}^n A_k = \prod_{k=1}^n \mathbb{P} A_k$. This follows from induction and the fact that $\mathbb{P} \bigcap_{k=1}^n A_k = \mathbb{P} A_n \cdot \mathbb{P} \bigcap_{k=1}^{n-1} A_k$ because $\mathcal{F}_n \perp \bigvee_{k \leq n-1} \mathcal{F}_k$, and $\bigcap_{k=1}^{n-1} A_k \in \bigvee_{k \leq n-1} \mathcal{F}_k$.

A $\sigma$-algebra $\mathcal{F} \subset \mathcal{A}$ is called ($\mathbb{P}$-)trivial if for any $A \in \mathcal{F}$, $\mathbb{P} A \in \{0, 1\}$.

Lemma 2.9. (i) A $\sigma$-algebra $\mathcal{F} \subset \mathcal{A}$ is trivial iff $\mathcal{F} \perp \mathcal{F}$. (ii) If $\mathcal{F}$ is trivial, and $\zeta$ is an $\mathcal{F}$-measurable random element in a separable metric space $S$, then $\zeta$ is a.s. constant.
Proof. (i) First suppose \( \mathcal{F} \) is trivial. Let \( A, B \in \mathcal{F} \). Then \( \mathbb{P}A \) and \( \mathbb{P}B \) equal to 0 or 1. If \( \mathbb{P}A = 0 \), then since \( A \cap B \subset A \), we have \( \mathbb{P}[A \cap B] = 0 = \mathbb{P}A \cdot \mathbb{P}B \). Similarly, if \( \mathbb{P}B = 0 \), then \( \mathbb{P}[A \cap B] = \mathbb{P}A \cdot \mathbb{P}B \). Now suppose \( \mathbb{P}A = \mathbb{P}B = 1 \). Then \( \mathbb{P}A^c = \mathbb{P}B^c = 0 \). Thus, \( \mathbb{P}[A^c \cup B^c] = 0 \). So \( \mathbb{P}[A \cap B] = 1 - \mathbb{P}[(A \cap B)^2] = 1 - \mathbb{P}[A^c \cup B^c] = 1 \). If \( \mathcal{F} \parallel \mathcal{F} \), then for any \( A \in \mathcal{F} \), \( \mathbb{P}A = \mathbb{P}(A \cap A) = (\mathbb{P}A)^2 \), which implies that \( \mathbb{P}A \in \{0,1\} \), and so \( \mathcal{F} \) is trivial.

(ii) Suppose \( \mathcal{F} \) is trivial. For each \( n \in \mathbb{N} \), we may partition \( S \) into mutually disjoint countably many Borel sets \( B_{n,j} \) of diameter \( < 1/n \). Fix \( n \in \mathbb{N} \). Since \( \mathbb{P}[\zeta \in B_{n,j}] \in \{0,1\} \) for each \( j \), and \( (B_{n,j}) \) is a partition of \( S \), there is \( j_n \) such that \( \mathbb{P}[\zeta \in B_{n,j_n}] = 1 \). So there is a null event \( N_n \) such that \( \zeta \in B_{n,j_n} \) on \( N_n^c \). Let \( N = \bigcup_n N_n \). Then \( N \) is a null set, and \( \zeta \in \bigcap_n B_{n,j_n} \) on \( N^c \). Since \( \text{diam}(B_{n,j_n}) < 1/n \) for all \( n \), \( \zeta \) is a constant on \( N^c \).

\[ \square \]

Lemma 2.11. Let \( \zeta \) and \( \eta \) be independent random elements in measurable spaces \( S \) and \( T \), and let \( f : S \times T \to \mathbb{R} \) be measurable. If \( f \geq 0 \), then \( \mathbb{E}f(\zeta, \eta) = \mathbb{E}[\mathbb{E}[f(s, \eta)]|_{s=\zeta}] \). Here the RHS means that we first fix \( s \in S \) and integrate the random variable \( f(s, \eta) \), which is a measurable function in \( s \in S \) by Lemma 1.38; then we compose it with \( \zeta \) to get a random variable, and integrate it. If we do not assume that \( f \geq 0 \), but assume that either \( \mathbb{E}|f(\zeta, \eta)| < \infty \) or \( \mathbb{E}[|f(s, \eta)||_{s=\zeta}] < \infty \), then the equality also holds.

Proof. This lemma essentially follows from Fubini’s theorem. We now only work on the case that \( f \geq 0 \). Let \( \mu \) and \( \nu \) be the laws of \( \zeta \) and \( \eta \), respectively. Since \( \zeta \parallel \eta \), by Lemma 2.10, \( \text{Law}(\zeta, \eta) = \mu \times \nu \). By Fubini’s theorem,

\[
\mathbb{E}f(\zeta, \eta) = \int f(s, t)\mu \times \nu(ds, dt) = \int \mu(ds) \int f(s, t)\nu(dt)
\]

\[
= \mathbb{E}\left[\int f(s, t)\nu(dt)|_{s=\zeta}\right] = \mathbb{E}[\mathbb{E}[f(s, \eta)]|_{s=\zeta}].
\]

The case without assuming \( f \geq 0 \) follows from linearity. \( \square \)

Corollary. For independent random variables \( \zeta_1, \ldots, \zeta_n \),

1. (i) If \( \zeta_1, \ldots, \zeta_n \in L^1 \), then \( \mathbb{E}\prod_{k=1}^n \zeta_k = \prod_{k=1}^n \mathbb{E}\zeta_k \);

2. (ii) If \( \zeta_1, \ldots, \zeta_n \in L^2 \), then \( \text{var}(\sum_{k=1}^n \zeta_k) = \sum_{k=1}^n \text{var}(\zeta_k) \).

Proof. By induction and Corollary 2.7, it suffices to prove the case \( n = 2 \). Suppose \( \zeta \parallel \eta \). To prove \( \mathbb{E}\zeta \eta = \mathbb{E}\zeta \mathbb{E}\eta \), we apply Lemma 2.11 with \( f(x, y) = xy \). For the variance, we note that \( \text{var}(\zeta + \eta) - (\text{var}(\zeta) + \text{var}(\eta)) = 2\text{cov}(\zeta, \eta) = 2\mathbb{E}(\zeta - \mathbb{E}\zeta)(\eta - \mathbb{E}\eta) = 2\mathbb{E}(\zeta - \mathbb{E}\zeta)(\eta - \mathbb{E}\eta) = 0 \), where the second equality holds because \( \zeta - \mathbb{E}\zeta \parallel \eta - \mathbb{E}\eta \). So \( \text{var}(\zeta + \eta) = \text{var}(\zeta) + \text{var}(\eta) \). \( \square \)

Corollary 2.12. Let \( \zeta, \eta \) be independent random elements in a measurable group. Then \( \text{Law}(\zeta + \eta) = \text{Law}(\zeta) \ast \text{Law}(\eta) \).
Proof. By Lemma 2.10, \( \text{Law}(\zeta, \eta) = \text{Law}(\zeta) \times \text{Law}(\eta) \). So \( \text{Law}(\zeta + \eta) \) equals the pushforward of \( \text{Law}(\zeta) \times \text{Law}(\eta) \) under the map \((x, y) \mapsto xy\), which is the convolution of \( \text{Law}(\zeta) \) and \( \text{Law}(\eta) \). \( \square \)

By an exercise, if \( \zeta_1, \ldots, \zeta_n \) are independent random variables with Bernoulli distribution \( B(p) \), then \( \zeta_1 + \cdots + \zeta_n \) has the binomial distribution \( B(n, p) \). Suppose \( \zeta_1 \) and \( \zeta_2 \) are independent random variables. If they have Poisson distributions \( \text{Pois}(\lambda_1) \) and \( \text{Pois}(\lambda_2) \), respectively, then \( \zeta_1 + \zeta_2 \) has Poisson distributions \( \text{Pois}(\lambda_1 + \lambda_2) \). If they have Normal distributions \( \text{N}(\mu_1, v_1) \) and \( \text{N}(\mu_2, v_2) \), respectively, then \( \zeta_1 + \zeta_2 \) has Normal distributions \( \text{N}(\mu_1 + \mu_2, v_1 + v_2) \).

We now study some zero-one laws. Given a sequence of \( \sigma \)-algebras \( F_1, F_2, \ldots \), the associated tail \( \sigma \)-algebra is defined by

\[
T = \bigcap_n \bigvee_{k \geq n} F_k = \bigcap_n \sigma\left( \bigcup_{k \geq n} F_k \right).
\]

**Example.** Suppose \( \zeta_1, \zeta_2, \ldots \) is a sequence of random variables, and \( F_n = \sigma(\zeta_n) \) for each \( n \). Let \( T \) be the tail \( \sigma \)-algebra. Then

(i) The set \( A_1 \) of \( \omega \in \Omega \) such that \( \lim_n \zeta_n(\omega) \) converges is measurable w.r.t. \( T \).

(ii) The set \( A_2 \) of \( \omega \in \Omega \) such that \( \sum_n \zeta_n(\omega) \) converges is measurable w.r.t. \( T \).

(iii) The set of \( \omega \in \Omega \) such that \( \frac{1}{n} \sum_{k=1}^n \zeta_k(\omega) \) converges is measurable w.r.t. \( T \).

(iv) If we define \( \eta_1 = \lim_n \zeta_n \) on \( A_1 \), then \( \eta_1 \) is \( A_1 \cap T \)-measurable.

(v) If we define \( \eta_2 = \sum_n \zeta_n \) on \( A_2 \), then \( \eta_2 \) may not be \( A_2 \cap T \)-measurable.

(vi) If we define \( \eta_3 = \lim_n \frac{1}{n} \sum_{k=1}^n \zeta_k \) on \( A_3 \), then \( \eta_3 \) is \( A_3 \cap T \)-measurable.

**Theorem 2.13** (Kolmogorov’s zero-one law). Let \( F_1, F_2, \ldots \) be independent \( \sigma \)-algebras in \( A \). Then the associated tail \( \sigma \)-algebra is trivial.

**Proof.** For \( n \in \mathbb{N} \), define \( T_n = \bigvee_{k \geq n} F_k \). Then \( T = \bigcap_n T_n \). By Corollary 2.7, for any \( n \), \( F_1, \ldots, F_n, T_n \) are independent. Since \( T \subset T_n \), \( T, F_1, \ldots, F_n \) are independent for all \( n \). Then we conclude that, \( T, F_1, F_2, \ldots \) are independent. By Corollary 2.7 again, we get \( T \subseteq \bigvee_{n=1}^\infty F_n \). Since \( T \subset \bigvee_{n=1}^\infty F_n \), we get \( T \subset T \). By Lemma 2.9 (i), \( T \) is trivial. \( \square \)

**Corollary 2.14.** Let \( \zeta_1, \zeta_2, \ldots \) be independent random variables. Let \( S_n = \sum_{k=1}^n \zeta_k \), \( n \in \mathbb{N} \). Then each of the sequences \( (\zeta_n) \), \( (S_n) \) and \( \left( \frac{1}{n} S_n \right) \) is either a.s. convergent or a.s. divergent. If \( (\zeta_n) \) or \( \left( \frac{1}{n} S_n \right) \) a.s. converges, then the limit is a.s. constant.

There is another zero-one law, which works best for the sum of independent and identically distributed (i.i.d.) sequences of random vectors.

A bijective map \( p : \mathbb{N} \to \mathbb{N} \) is called a finite permutation of \( \mathbb{N} \) if there is \( N \) such that \( p_n = n \) for \( n > N \). A finite permutation \( p \) of \( \mathbb{N} \) induces a bijective map \( T_p : S^\infty \to S^\infty \) given by \( T_p(s_1, s_2, \ldots) = (s_{p_1}, s_{p_2}, \ldots) \). A set \( I \subset S^\infty \) is called symmetric if \( T_p^{-1} I = I \) for all finite permutation \( p \) of \( \mathbb{N} \). Let \( (S, \mathcal{S}) \) be a measurable space. Then for every \( p \), \( \mathcal{I}_p := \{ I \in \mathcal{S}^\infty : T_p^{-1} I = I \} \) is a \( \sigma \)-algebra. So the set of symmetric \( I \in \mathcal{S}^\infty \) form a \( \sigma \)-algebra \( \mathcal{I} = \bigcap_p \mathcal{I}_p \), which is called the permutation invariant \( \sigma \)-algebra in \( \mathcal{S}^\infty \).
Example. Suppose \( G \) is an Abelian measurable group (e.g. \( \mathbb{R}^d \)). Let \( B \subset G \) be measurable. Then the set
\[
E_B = \{(v_1, v_2, \ldots) \in G : \sum_{k=1}^{n} v_k \in B \text{ for infinitely many } n\}
\]
belongs to the permutation invariant \( \sigma \)-algebra.

Theorem 2.15 (Hewitt-Savage zero-one law). Let \( \zeta_1, \zeta_2, \ldots \) be an i.i.d. sequence of random elements in a measurable space \((S, \mathcal{S})\), and let \( \zeta = (\zeta_1, \ldots, \zeta_n) \). Let \( \mathcal{I} \) be the permutation invariant \( \sigma \)-algebra in \( \mathcal{S}^\infty \). Then \( \zeta^{-1} \mathcal{I} \) is trivial.

Lemma 2.16. Given any \( \sigma \)-algebras \( \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \) in \( S \), a probability measure \( \mu \) on \( \bigvee_n \mathcal{F}_n \), and a set \( A \in \bigvee_n \mathcal{F}_n \), there exist a sequence \( A_1, A_2, \ldots \in \bigcup_n \mathcal{F}_n \) with \( \mu(A_n \Delta A) \to 0 \).

Proof. Let \( \mathcal{D} \) denote the set of \( A \in \bigvee_n \mathcal{F}_n \) with the stated property. Then \( \mathcal{D} \) is a \( \lambda \)-system containing the \( \pi \)-system \( \mathcal{C} := \bigcup \mathcal{F}_n \). Here we use the fact that \( \mu(A \Delta B) = \|1_A - 1_B\|_1 \). By monotone class theorem, \( \mathcal{D} \) contains \( \sigma(\mathcal{C}) = \bigvee_n \mathcal{F}_n \). \( \Box \)

Proof of Theorem 2.15. Let \( \mu = \mathbb{P} \circ \zeta^{-1} \). Set \( \mathcal{F}_n = \mathcal{S}^n \times S^\infty \), \( n \in \mathbb{N} \). Note that \( \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \), and \( \bigvee_n \mathcal{F}_n = \mathcal{S}^\infty \supset \mathcal{I} \). For any \( I \in \mathcal{I} \), by Lemma 2.16 there is a sequence \( I_n \) of the form \( B_n \times S^\infty \) with \( B_n \in \mathcal{F}_n \) such that \( \mu(I_n \Delta I) \to 0 \), and so \( \mu I_n \to \mu I \). Writing \( \tilde{I}_n = S^n \times B_n \times S^\infty \), then by the symmetry of \( \mu \) and \( I \), we have \( \mu \tilde{I}_n = \mu I_n \) and \( \mu(\tilde{I}_n \Delta I) = \mu(I_n \Delta I) \to 0 \). Hence
\[
\mu((I_n \cap \tilde{I}_n) \Delta I) \leq \mu(I_n \Delta I) + \mu(\tilde{I}_n \Delta I) \to 0
\]
because \( (A \cap B) \Delta C \subset (A \Delta C) \cup (B \Delta C) \). So \( \mu(I_n \cap \tilde{I}_n) \to \mu I \). By independence of \( \zeta_k \), we have
\[
\mu(I_n \cap \tilde{I}_n) = \mathbb{P}[(\zeta_1, \ldots, \zeta_n) \in B_n, (\zeta_{n+1}, \ldots, \zeta_{2n}) \in B_n] = \mathbb{P}[(\zeta_1, \ldots, \zeta_n) \in B_n]^2 = \mu(I_n)^2.
\]
So \( \mu(I_n \cap \tilde{I}_n) \to \mu(I)^2 \). Then we get \( \mu I = (\mu I)^2 \) and so \( \mu I \in \{0, 1\} \). \( \Box \)

Corollary 2.17. Let \( \zeta_1, \zeta_2, \ldots \) be i.i.d. random vectors in \( \mathbb{R}^d \), and put \( S_n = \zeta_1 + \cdots + \zeta_n \). Then for any \( B \in \mathcal{B}(\mathbb{R}^d) \), \( \mathbb{P}\{S_n \in B \text{ i.o.}\} = 0 \) or 1.

Note that Kolmogorov’s zero-one law does not apply here because \( \{S_n \in B \text{ i.o.}\} \) is not a tail event.

The sequence \( (S_n) \) is called a random walk on \( \mathbb{R}^d \). For a more specific example, we may consider the case that every \( \zeta_k \) has the distribution
\[
\frac{1}{2d} \sum_{\sigma \in \{+,-\}} \sum_{j=1}^{d} \delta_{\sigma e_j},
\]
where \( e_j \) is the vector in \( \mathbb{R}^d \) whose \( j \)-th component is 1 and all other components are 0. In this case \( (S_n) \) is called a simple random walk on \( \mathbb{Z}^d \). By Corollary 2.17, for every \( v_0 \in \mathbb{Z}^d \), \( \mathbb{P}\{S_n = v_0 \text{ i.o.}\} = 0 \) or 1. By translation invariance of \( \mathbb{Z}^d \), one easily see that the value of \( \mathbb{P}\{S_n = v_0 \text{ i.o.}\} \) depends only on \( d \). If the value is 1, the random walk is called \textit{recurrent}; if the value is 0, the random walk is called \textit{transient}. It turns out (not easy!) that, when \( d \leq 2 \), the random walk is recurrent, and when \( d \geq 3 \), the random walk is transient.
Theorem 2.18 (Borel-Cantelli lemma). Let $A_1, A_2, \cdots \in \mathcal{A}$. Then $\sum_n P(A_n) < \infty$ implies that $P(A_n \ i.o.) = 0$, and when the $A_n$ are independent, $P(A_n \ i.o.) = 0$ implies that $\sum_n P(A_n) < \infty$.

Proof. We have proved the first assertion. Now suppose $A_n$ are independent. Then $A_n^c$ are also independent. For any $n < N \in \mathbb{N}$,

$$1 - P \left( \bigcup_{m=n}^{N} A_m \right) = P \left( \bigcap_{m=n}^{N} A_m^c \right) = \prod_{m=n}^{N} (1 - P(A_m)).$$

Letting $N \to \infty$, we get

$$1 - P \left( \bigcup_{m=n}^{\infty} A_m \right) = \prod_{m=n}^{\infty} (1 - P(A_m)).$$

If $P(A_n \ i.o.) = 0$, then there is $n$ such that $1 - P \left( \bigcup_{m=n}^{\infty} A_m \right) > 0$, which implies by calculus that $\sum_{m=n}^{\infty} P(A_m) < \infty$, and so $\sum_{n} P(A_n) < \infty$. \hfill \Box

For $x = (x_1, \ldots, x_d)$ and $y = (y_1, \ldots, y_d)$ in $\mathbb{R}^d$, we write $x \leq y$ (resp. $x < y$) if $x_k \leq y_k$ (resp. $x_k < y_k$) for all $1 \leq k \leq d$. For $x < y \in \mathbb{R}^d$, we define

$$(-\infty, y] = \{z \in \mathbb{R}^d : z \leq y \} = \prod_{k=1}^{d} (-\infty, y_k], \quad (x, y] = \{z \in \mathbb{R}^d : x < z \leq y \} = \prod_{k=1}^{d} (x_k, y_k].$$

For a random vector $\zeta$ in $\mathbb{R}^d$, we define the associated distribution function $F$ by

$$F(x) = P(\zeta_j \leq x_j, 1 \leq j \leq d) = \text{Law}(\zeta)(-\infty, x].$$

By a monotone argument, we get

Lemma 2.3. Two random vectors in $\mathbb{R}^d$ have the same distribution iff they have the same distribution function.

We may use $F$ to calculate $\mu(x, y]$. For $d = 1$, $\mu(x, y] = F(y) - F(x)$. For $d \geq 2$, we need an inclusion-exclusion argument.

Exercise. Prove that for any $x < y \in \mathbb{R}^d$,

$$\mu(x, y] = \sum_{S \subseteq \{1, \ldots, d\}} (-1)^{|S|} F(z^S), \quad (2.3)$$

where $z^S \in \mathbb{R}^d$ such that $z_k^S = x_k$ if $k \in S$ and $z_k^S = y_k$ if $k \notin S$.

Then $F$ satisfies the following properties.

(i) $F(x, y] \geq 0$ for every $x < y \in \mathbb{R}^d$, where we define $F(x, y]$ to be the RHS of (2.3).

(ii) $F$ is right-continuous in the sense that $\lim_{x \downarrow y} F(x) = F(y)$ for any $y \in \mathbb{R}^d$, where $x \downarrow y$ means that $x_k > y_k$ and $x_k \to y_k$ for all $1 \leq k \leq d$. 

42
(iii) \( \lim_{x_k \to -\infty} F(x) = 0. \)

(iv) \( \lim_{x_k \to \infty} F(x) = 1. \)

Here (ii)-(iv) follow from the continuity of \( \mu \) and the fact that \( \mu(\mathbb{R}^d) = 1. \)

**Theorem 2.25-2.26.** If \( F \) satisfies (i-iii), then it is the distribution function of some \( \sigma \)-finite measure \( \mu \) on \( \mathbb{R}^d. \) If \( F \) also satisfies (iv), then \( \mu \) is a probability measure.

**Proof.** We define a ring \( \mathcal{R} \) on \( \mathbb{R}^d \) to be the class of disjoint unions of sets of the form \((x, y]\) for \( x < y \in \mathbb{R}^d. \) Define \( \mu : \mathcal{R} \to \mathbb{R}_+ \) such that if \( A \) has a disjoint union expression \( \bigcup_{j=1}^{m} (x^j, y^j], \)

\[
\mu A = \sum_{j=1}^{m} F(x^j, y^j).
\]

Such \( \mu \) is well defined and satisfies finitely additivity. We then show that \( \mu \) is a pre-measure. Suppose \( A_1 \supset A_2 \supset \cdots \in \mathcal{R} \) with \( \mu A_n \geq \varepsilon > 0 \) for all \( n. \) We need to show that \( \bigcap_n A_n \neq \emptyset. \)

Let \( A''_n = A'_1 \cap \cdots \cap A'_{n}. \) Then \( \overline{A''_n} \subseteq A_n \) for each \( n, \) and \( A''_1 \supset A''_2 \supset \cdots. \) Since \( A''_n \subset \bigcup_{k=1}^{n} (A_k \setminus A'_k), \)

we get \( \mu(A_n \setminus A'_{n}) \leq \sum_{k=1}^{n} \mu(A_k \setminus A'_k) < \sum_{k=1}^{n} \varepsilon = \varepsilon. \)

From \( \mu A_n > \varepsilon \) we get \( \mu A''_{n} > 0, \) and so \( A''_{n} \neq \emptyset. \) Since each \( A''_{n} \) is compact and \( A''_1 \supset A''_2 \supset \cdots, \) we get \( \bigcap_n A''_n \neq \emptyset, \)

which together with \( \overline{A''_n} \subseteq A_n \) implies that \( \bigcap_n A_n \neq \emptyset. \) So \( \mu \) is a pre-measure on \( \mathcal{R}. \) We may then use Carathéodory extension theorem to extend \( \mu \) to a measure on \( \mathbb{R}^d. \) It is \( \sigma \)-finite because \( \mu(x, x+1] < \infty \) for every \( x \in \mathbb{Z}^d, \) where \( 1 = (1, \ldots, 1). \)

By (iii) we have, for every \( y \in \mathbb{R}^d, \)

\[
F(y) = \lim_{x_k \to -\infty} F(x, y) = \lim_{x_k \to -\infty} \mu(x, y) = \mu(-\infty, y].
\]

So \( F \) is the distribution function of \( \mu. \) If (iv) holds, then

\[
\mu_{\mathbb{R}^d} = \lim_{n \to \infty} \mu(-\infty, (n, \ldots, n)] = \lim_{n \to \infty} F(n, \ldots, n) = 1,
\]

which implies that \( \mu \) is a probability measure.

**Exercise.** Problems 4, 5, 8, 12 of Exercises of Chapter 2.

### 3 Random Sequences, Series, and Averages

We still fix a probability space \((\Omega, \mathcal{A}, \mathbb{P}), \)

and assume that all random elements are defined on this space. We will study several different concepts of convergence of random variables: almost sure convergence, \( \zeta_n \to \zeta \) a.s., convergence in probability, \( \zeta_n \to^p \zeta, \)

convergence in distribution, \( \zeta_n \overset{d}{\to} \zeta, \) and convergence in \( L^p. \)
**Definition.** Let $\zeta, \zeta_1, \zeta_2, \ldots$ be random elements in a metric space $(S, \rho)$.

(i) We say that $\zeta_n$ converges almost surely to $\zeta$, and write $\zeta_n \xrightarrow{\text{a.s.}} \zeta$, if there is a null event $N$ such that $\rho(\zeta_n(\omega), \zeta(\omega)) \to 0$ for every $\omega \in \Omega \setminus N$.

(ii) We say that $\zeta_n$ converges in probability to $\zeta$, and write $\zeta_n \xrightarrow{\text{P}} \zeta$, if for every $\varepsilon > 0$, $\lim_{n \to \infty} \mathbb{P}\{\rho(\zeta_n, \zeta) > \varepsilon\} = 0$.

(iii) We say that $\zeta_n$ converges in distribution to $\zeta$, and write $\zeta_n \xrightarrow{\text{d}} \zeta$, if for every $f \in C_b(S, \mathbb{R})$, the space of bounded real-valued continuous functions on $S$, we have $\mathbb{E}f(\zeta_n) \to \mathbb{E}f(\zeta)$.

(iv) In the case that $S = \mathbb{R}$, we say that $\zeta_n$ converges to $\zeta$ in $L^p$ for some $p > 0$, if $\zeta, \zeta_1, \zeta_2, \ldots \in L^p$ and $\|\zeta_n - \zeta\|_p = \left(\mathbb{E}[(\zeta_n - \zeta)^p]\right)^{1/p} \to 0$.

**Lemma 3.1 (Chebyshev inequality).** For any measurable $\zeta : \Omega \to \mathbb{R}_+$ and $r > 0$,

$$\mathbb{P}\{\zeta \geq r\} \leq \frac{1}{r} \mathbb{E}\zeta.$$

**Proof.** Since $\zeta \geq r \mathbf{1}_{\{\zeta \geq r\}}$, we get $\mathbb{E}\zeta \geq \mathbb{E}(r \mathbf{1}_{\{\zeta \geq r\}}) = r\mathbb{P}\{\zeta \geq r\}$. \qed

**Exercise.** Prove that $\zeta_n \xrightarrow{\text{a.s.}} \zeta$ in $L^p$ for some $p > 0$ implies that $\zeta_n \xrightarrow{\text{P}} \zeta$.

**Lemma.** For $\zeta, \zeta_1, \zeta_2, \ldots$ in the above definition, $\zeta_n \xrightarrow{\text{P}} \zeta$ iff $\mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \to 0$.

**Proof.** For every $\varepsilon \in (0, 1)$, from $\varepsilon \mathbf{1}_{\{\rho(\zeta_n, \zeta) > \varepsilon\}} \leq 1 \land \rho(\zeta_n, \zeta) \leq \mathbf{1}_{\{\rho(\zeta_n, \zeta) > \varepsilon\}} + \varepsilon$, we get

$$\varepsilon \mathbb{P}\{\rho(\zeta_n, \zeta) > \varepsilon\} \leq \mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \leq \mathbb{P}\{\rho(\zeta_n, \zeta) > \varepsilon\} + \varepsilon.$$

These inequalities imply the equivalence. \qed

**Remark.** The lemma means that the convergence in probability is determined by a metric

$$\rho_N(\zeta, \eta) = \mathbb{E}[1 \land \rho(\zeta, \eta)].$$

This is in general not true for almost surely convergence.

**Lemma 3.2 (subsequence criterion).** Let $\zeta, \zeta_1, \zeta_2, \ldots$ be as before. Then $\zeta_n \xrightarrow{\text{P}} \zeta$ iff every subsequence $N' \subset \mathbb{N}$ has a further subsequence $N'' \subset N'$ such that $\zeta_n \xrightarrow{\text{a.s.}} \zeta$ a.s. along $N''$. In particular, the almost sure convergence implies the convergence in probability.

**Proof.** Suppose $\zeta_n \xrightarrow{\text{P}} \zeta$. Then $\mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \to 0$ by the above lemma. Suppose $N' \subset \mathbb{N}$. Then $\mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \to 0$ along $N'$. We may then choose a subsequence $N'' \subset N'$ such that $\sum_{n \in N''} \mathbb{E}[1 \land \rho(\zeta_n, \zeta)] < \infty$. By monotone convergence theorem, we get

$$\mathbb{E}\left[\sum_{n \in N''} 1 \land \rho(\zeta_n, \zeta)\right] < \infty,$$
which implies that a.s. \( \sum_{n \in N'} 1 \land \rho(\zeta_n, \zeta) < \infty \). So a.s. \( \zeta_n \to \zeta \) along \( N'' \). On the other hand, suppose \( \zeta_n \not{\xrightarrow{P}} \zeta \). Then \( \mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \neq 0 \). So there is \( \varepsilon > 0 \) and a subsequence \( N' \subset \mathbb{N} \) such that \( \mathbb{E}[1 \land \rho(\zeta_n, \zeta)] > \varepsilon \) for any \( n \in N' \). It there is a further subsequence \( N'' \subset N' \) such that \( \zeta_n \to \zeta \) a.s. along \( N'' \), then since \( 1 \land \rho(\zeta_n, \zeta) \to 0 \) a.s. along \( N'' \), by dominated convergence theorem, \( \mathbb{E}[1 \land \rho(\zeta_n, \zeta)] \to 0 \) along \( N'' \), which is a contradiction.

Finally, if \( \zeta_n \to \zeta \) a.s. then for any \( N' \subset \mathbb{N} \), \( \zeta_n \to \zeta \) a.s. along \( N' \). So we get \( \zeta_n \overset{P}{\to} \zeta \). \( \square \)

**Remark.** From Lemma 3.2, we see that the condition that \( \zeta_n \to \zeta \) a.s. in dominated convergence theorem can be further weakened to \( \zeta_n \overset{P}{\to} \zeta \). This means that if \( \zeta_n \to P \zeta, |\zeta_n| \leq \eta \) for all \( n \), and \( \mathbb{E}\eta < \infty \), then \( \mathbb{E}\zeta_n \to \mathbb{E}\zeta \).

**Example.** We may find a sequence of random variables \( \zeta_n \) on \(([0,1], \lambda)\) such that \( \zeta_n \overset{P}{\to} 0 \) but \( \zeta_n \) does not a.s. converge to 0. In fact, we may choose \( \zeta_n = 1_{A_n} \), where

\[
A_1 = [0,1], \quad A_2 = [0,1/2], \quad A_3 = [1/2,1],
\]

\[
A_4 = [0,1/4], \quad A_5 = [1/4,2/4], \quad A_6 = [2/4,3/4], \quad A_7 = [3/4,1], \ldots
\]

The general formula is: for \( 2^k \leq n \leq 2^{k+1} - 1 \), \( \zeta_k = 1_{[\frac{n}{2^k} - 1, \frac{n}{2^k}] - 1} \). We observe that \( \|\zeta_n\|_1 = 2^{-k} \) if \( 2^k \leq n \leq 2^{k+1} - 1 \). So \( \zeta_n \to 0 \) in \( L^1 \), which implies that \( \zeta_n \overset{P}{\to} 0 \). However, for every \( t \in [0,1] \), there are infinitely many \( n \) such that \( \zeta_n(t) \to 1 \). So \( \zeta_n \) does not a.s. tend to 0.

**Lemma 3.3.** Let \( S \) and \( T \) be two metric spaces. Suppose \( \zeta_n \overset{P}{\to} \zeta \) in \( S \), and \( f : S \to T \) be continuous. If \( \zeta_n \overset{P}{\to} \zeta \) in \( S \), then \( f(\zeta_n) \overset{P}{\to} f(\zeta) \) in \( T \).

**Proof.** By Lemma 3.2, every subsequence \( N' \subset \mathbb{N} \) contains a further subsequence \( N'' \subset N' \) such that \( \zeta_n \to \zeta \) a.s. in \( S \) along \( N'' \). By the continuity of \( f \), we see that \( f(\zeta_n) \to f(\zeta) \) a.s. in \( T \) along \( N'' \). Thus, by Lemma 3.2 \( f(\zeta_n) \overset{P}{\to} f(\zeta) \) in \( T \). \( \square \)

**Corollary 3.5.** Let \( \zeta, \zeta_1, \zeta_2, \ldots \) and \( \eta, \eta_1, \eta_2, \ldots \) be random variables with \( \zeta_n \overset{P}{\to} \zeta \) and \( \eta_n \overset{P}{\to} \eta \). Then \( a\zeta_n + b\eta_n \overset{P}{\to} a\zeta + b\eta \) for any \( a, b \in \mathbb{R} \) and \( \zeta_n \eta_n \overset{P}{\to} \zeta \eta \). Furthermore, \( \zeta_n/\eta_n \overset{P}{\to} \zeta/\eta \) whenever \( \eta_n \) and \( \eta \) do not take value zero.

**Proof.** From \( \zeta_n \overset{P}{\to} \zeta \) and \( \eta_n \overset{P}{\to} \eta \) we get \( (\zeta_n, \eta_n) \overset{P}{\to} (\zeta, \eta) \). We may then apply Lemma 3.3 to continuous functions \( \mathbb{R}^2 \ni (x,y) \mapsto ax + by \in \mathbb{R}, \mathbb{R}^2 \ni (x,y) \mapsto xy \), and \( \mathbb{R} \times (\mathbb{R} \setminus \{0\}) \ni (x,y) \mapsto x/y \), respectively. \( \square \)

**Definition.** For random elements \( \zeta_1, \zeta_2, \ldots \) in a metric space \((S, \rho)\), we say that \((\zeta_n)\) is a Cauchy sequence in probability if for any \( \varepsilon > 0 \), \( \mathbb{P}\{\rho(\zeta_n, \zeta_m) > \varepsilon\} \to 0 \) as \( n, m \to \infty \). Using a similar argument as before, we can show that this is equivalent to that \( \mathbb{E}[1 \land \rho(\zeta_n, \zeta_m)] \to 0 \) as \( n, m \to \infty \).
If \( \zeta_n \overset{P}{\to} \zeta \), then \( \mathbb{E}[1 \wedge \rho(\zeta_n, \zeta)] \to 0 \) as \( n \to \infty \). By triangle inequality, we get \( \mathbb{E}[1 \wedge \rho(\zeta_n, \zeta_m)] \to 0 \) as \( n, m \to \infty \), which implies that \( (\zeta_n) \) is a Cauchy sequence in probability. The converse is true if \((S, \rho)\) is complete. This is the lemma below.

**Lemma 3.6.** If \((S, \rho)\) is complete, then \( (\zeta_n) \) is a Cauchy sequence in probability iff \( \zeta_n \overset{P}{\to} \zeta \) for some random element \( \zeta \) in \( S \).

**Proof.** We have proved the “if” part. Now we prove the “only if” part. Assume that \( (\zeta_n) \) is a Cauchy sequence in probability. We may choose a subsequence \( (n_k) \) of \( \mathbb{N} \) such that \( \mathbb{E}[1 \wedge \rho(\zeta_{n_k}, \zeta_{n_k+1})] \leq 2^{-k} \) for all \( k \in \mathbb{N} \). Then we have

\[
\mathbb{E}\left[\sum_k 1 \wedge \rho(\zeta_{n_k}, \zeta_{n_k+1})\right] \leq \sum_k 2^{-k} < \infty,
\]

which implies that a.s. \( \sum_k 1 \wedge \rho(\zeta_{n_k}, \zeta_{n_k+1}) < \infty \), and so \( \sum_k \rho(\zeta_{n_k}, \zeta_{n_k+1}) < \infty \). So almost surely \( (\zeta_{n_k}) \) is a Cauchy sequence in \( S \). By the completeness of \( S \), there is a random element \( \zeta \) in \( S \) such that a.s. \( \zeta_{n_k} \to \zeta \). Thus, \( \mathbb{E}[1 \wedge \rho(\zeta_{n_k}, \zeta)] \to 0 \) as \( k \to \infty \). To see that \( \zeta_n \overset{P}{\to} \zeta \), write

\[
\mathbb{E}[1 \wedge \rho(\zeta_m, \zeta)] \leq \mathbb{E}[1 \wedge \rho(\zeta_n, \zeta)] + \mathbb{E}[1 \wedge \rho(\zeta, \zeta_n)],
\]

and use the convergence of the RHS to 0 as \( m, k \to \infty \). \( \square \)

This lemma shows that the space of random elements on \( S \) with metric \( \rho_V(\zeta, \eta) = \mathbb{E}[1 \wedge \rho(\zeta, \eta)] \) is complete when \( S \) is complete.

**Lemma 3.7.** The convergence in probability implies the convergence in distribution.

**Proof.** Suppose \( \zeta_n \overset{P}{\to} \zeta \) in \( S \), and \( f \in C_b(S) \). Then \( f(\zeta_n) \overset{P}{\to} f(\zeta) \) by Lemma 3.3. By monotone convergence theorem (for convergence in probability), we have \( \mathbb{E}f(\zeta_n) \to \mathbb{E}f(\zeta) \). So \( \zeta_n \overset{d}{\to} \zeta \). \( \square \)

**Definition.** Let \( \mu, \mu_1, \mu_2, \ldots \) be probability measures on a metric space \((S, \rho)\). We say that \( \mu_n \) converges weakly to \( \mu \), and write \( \mu_n \overset{w}{\to} \mu \), if for any \( f \in C_b(S, \mathbb{R}) \), \( \mu_n f \to \mu f \).

**Remark.** By Lemma 1.22, \( \mathbb{E}f(\zeta) = \text{Law}(\zeta)f \). So \( \zeta_n \overset{d}{\to} \zeta \) iff \( \text{Law}(\zeta_n) \overset{w}{\to} \text{Law}(\zeta) \). This means that the convergence in distribution depends only on the distributions of \( \zeta \) and \( \zeta_n \) (and not on the exact value of \( \zeta_n(\omega) \) and \( \zeta(\omega) \)).

**Lemma 3.25** (Portmanteau). For any probability measures \( \mu, \mu_1, \ldots, \mu_n \) on a metric space \((S, \rho)\), these conditions are equivalent:

1. \( \mu_n \overset{w}{\to} \mu \);
2. \( \lim \inf_n \mu_n G \geq \mu G \) for any open set \( G \subset S \);
3. \( \lim \sup_n \mu_n F \leq \mu F \) for any closed set \( F \subset S \);
(iv) \( \lim_n \mu_n B = \mu B \) for any \( B \in \mathcal{B}(S) \) with \( \mu \partial B = 0 \).

A set \( B \) satisfying the condition in (iv) is called a \( \mu \)-continuity set.

**Example**. Suppose \((x_n)\) is a sequence in \( S \) and \( x_n \to x_0 \in S \). Then we have \( \delta_{x_n} \xrightarrow{w} \delta_{x_0} \) because for any \( f \in C_b \),

\[
\delta_{x_n} = f(x_n) \to f(x_0) = \delta_{x_0} f.
\]

Suppose \( G \subset S \) is open, and \( x_0 \in \partial G \), then we can find a sequence \((x_n)\) in \( G \) such that \( x_n \to x_0 \). Then \( \delta_{x_0} G = 0 \) but \( \delta_{x_n} G = 1 \) for each \( n \). So we do not get a strict inequality in (ii).

**Proof.** Assume (i), and fix an open set \( G \subset S \). Let \( f_m(x) = 1 \wedge (m\rho(x, G^c)) \), \( m \in \mathbb{N} \). Then \( f_m \in C_b(S) \) and \( f_m \uparrow 1_G \). For each \( m \), by \( \mu_n \xrightarrow{w} \mu \), we have \( \mu f_m = \lim_n \mu_n f_m \leq \liminf \mu_n G \).

Sending \( m \to \infty \) and using monotone convergence, we then get (ii). The equivalence between (ii) and (iii) are clear from taking complements. Now assume (ii) and (iii). For any \( B \in \mathcal{B} \),

\[
\mu B^c \leq \liminf \mu_n B^c \leq \liminf \mu_n B \leq \limsup \mu_n B \leq \limsup B \leq \mu B.
\]

If \( \mu \partial B = 0 \), then \( \mu \overline{B} = \mu B^c = \mu B \), and (iv) follows.

Assume (iv), and fix a closed set \( F \subset S \). Write \( F^c = \{ s \in S : \rho(s, F) < \varepsilon \} \). Then the sets \( \partial F^c \subset \{ s \in S : \rho(s, F) = \varepsilon \} \), \( \varepsilon > 0 \), are disjoint. So there are at most countably many \( \varepsilon > 0 \) such that \( \mu \partial F^c = 0 \). We can find a positive sequence \( \varepsilon_m \to 0 \) such that for every \( m \), \( \mu \partial F^c \leq 0 \). So \( \mu F^c \leq \lim n \mu_n F^c \geq \limsup \mu_n F \). Sending \( m \to \infty \), we get (iii). Finally, assume (ii) and let \( f : S \to \mathbb{R}_+ \) be continuous. By Lemma 2.4 and Fatou’s lemma,

\[
\mu f = \int_0^\infty \mu \{ f > t \} dt \leq \int_0^\infty \liminf \mu_n \{ f > t \} dt \leq \liminf \int_0^\infty \mu_n \{ f > t \} dt = \liminf \mu_n f.
\]

Suppose now \( f \in C_b(S) \) and \( |f| \leq c \). Applying the above formula to \( c \pm f \), we get \( c \pm \mu f \leq \liminf \{ c \pm \mu_n f \} \), which implies \( \lim_n \mu_n f = \mu f \), i.e., (i) holds.

**Exercise.** Let \( \mu, \mu_1, \mu_2, \ldots \) be probability measures on \( \mathbb{R}^d \). Let \( F, F_1, F_2, \ldots \) be their distribution functions. Prove that \( \mu_n \xrightarrow{w} \mu \) iff for any continuity point \( x \) of \( F \), \( F_n(x) \to F(x) \).

**Definition.** A family of probability measures \( \mu_t, t \in T \), on a topological space \( S \) is called tight, if for any \( \varepsilon > 0 \), there is a compact set \( K \subset S \) such that \( \mu_t(S \setminus K) < \varepsilon \) for any \( t \in T \).

Suppose \((S, \rho)\) is a metric space. For \( x \in S \) and \( \varepsilon > 0 \), let \( B(x, \varepsilon) = \{ y \in S : \rho(x, y) < \varepsilon \} \). For \( A \subset S \) and \( \varepsilon > 0 \), let

\[
A^\varepsilon = \bigcup_{x \in A} B(x, \varepsilon) = \{ y \in S : \rho(y, A) < \varepsilon \}.
\]

We now state some results about weak convergence without proofs.

**Theorem 14.3** (Prokhorov’s theorem). Let \((S, \rho)\) be a separable metric space. Then
(i) The Prokhorov metric \( \rho_* \) on the space \( \mathcal{P}(S) \) defined by

\[
\rho_*(\mu, \nu) = \inf \{ \varepsilon > 0 : \mu A \leq \nu A^\varepsilon + \varepsilon \text{ and } \nu A \leq \mu A^\varepsilon + \varepsilon \text{ for any } A \in \mathcal{B}(S) \}
\]

is a metric such that the weak convergence of probability measures on \( S \) is equivalent to the convergence w.r.t. the Prokhorov metric.

(ii) A tight family is relatively sequential compact w.r.t the weak convergence, i.e., every sequence in the family contains a weak convergent subsequence.

(iii) If \( S \) is complete, then \( (\mathcal{P}(S), \rho_*) \) is complete and every relatively compact subset of \( \mathcal{P}(S) \) is a tight family.

This lemma tells us that the weak convergence is induced by some explicitly defined metric, and if \( S \) is complete, then a tight family is equivalent to a relatively compact set w.r.t. weak convergence.

In the case that \( S = \mathbb{R}^d \), we sketch a proof of (ii) as follows. Suppose \( \mu_1, \mu_2, \ldots \) is a sequence of probability measures on \( \mathbb{R}^d \). Let \( F_1, F_2, \ldots \) be the distribution functions. Since \( 0 \leq F_n \leq 1 \), for every \( x \in \mathbb{Q}^d \), \( (F_n(x)) \) contains a convergent subsequence. By a diagonal argument and passing to a subsequence, we may assume that \( (F_n(x)) \) converges for each \( x \in \mathbb{Q}^d \). Let \( \bar{F}(x), x \in \mathbb{Q}^d \), be the limit function. Such \( \bar{F} \) is non-decreasing on \( \mathbb{Q}^d \). We use \( \bar{F} \) to define a function \( F \) on \( \mathbb{R}^d \) such that \( F(x) = \lim_{\mathbb{Q}^d \ni y \downarrow x} \bar{F}(y), x \in \mathbb{R}^d \). Then \( F \) is non-decreasing and right-continuous, and \( F_n(x) \to F(x) \) for each continuity point \( x \) of \( F \). If \( \{\mu_n\} \) is tight, then \( F \) is the distribution function of some probability measure \( \mu \), which is the weak limit of \( \mu_n \).

To understand the Prokhorov metric, suppose \( X \) and \( Y \) are two random elements in \( S \) defined on the same probability space \((\Omega, \mathcal{A}, \mathbb{P})\) such that

\[
\mathbb{P}\{\rho(X, Y) > \varepsilon\} < \varepsilon. \tag{3.1}
\]

Then it is straightforward to check that \( \rho_*(\text{Law}(X), \text{Law}(Y)) < \varepsilon \). The converse is not true, but we have the following coupling theorem, whose proof is omitted.

**Theorem** (coupling theorem). If \( \rho_*(\mu, \nu) < \varepsilon \), then there are a probability space \((\Omega, \mathcal{A}, \mathbb{P})\) and two random elements \( X, Y \) in \( S \) defined on \( \Omega \) such that \( \text{Law}(X) = \mu, \text{Law}(Y) = \nu \), and (3.1) holds.

From Lemma 3.7, \( \zeta_n \xrightarrow{\mathbb{P}} \zeta \) implies that \( \text{Law}(\zeta_n) \xrightarrow{\text{w}} \text{Law}(\zeta) \) and \( \zeta_n \xrightarrow{d} \zeta \). We have a converse statement in the following sense. We omit its proof.

**Theorem 3.30** (Skorokhod’s representation theorem). Let \( \mu, \mu_1, \mu_2, \ldots \) be probability measures on a separable metric space \((S, \rho)\). Then there exist a probability space \((\Omega, \mathcal{A}, \mathbb{P})\) and random elements \( \zeta, \zeta_1, \zeta_2, \ldots \) in \( S \) defined on \( \Omega \) such that \( \text{Law}(\zeta) = \mu, \text{Law}(\zeta_n) = \mu_n \), and \( \zeta_n \to \zeta \) pointwise.

**Exercise**. Suppose \( \zeta_n \xrightarrow{d} \zeta \) and \( \text{Law}(\zeta) \) is a point mass. Prove that \( \zeta_n \xrightarrow{\mathbb{P}} \zeta \).
There are other types of convergence of measures, such as the strong convergence: \( \mu_n A \to \mu A \) for every \( A \in \mathcal{A} \), and an even stronger convergence: the total variation convergence:

\[
\|\mu_n - \mu\|_{TV} := 2 \sup_{A \in \mathcal{A}} |\mu A - \nu A| \to 0.
\]

They are stronger than the weak convergence, but do not rely on the topology of \( S \).

**Example.** Let \( S \) be a metric space. Let \((x_n)\) be a sequence in \( S \) that converges to \( x_0 \). Suppose \( x_n \neq x_0 \) for all \( n \). Then \( \delta_{x_n} \) converges to \( \delta_{x_0} \) weakly but not strongly. If we take \( A = \{x_0\} \), then \( \delta_{x_n} A = 0 \) for all \( n \) but \( \delta_{x_0} A = 1 \).

**Exercise.** Let \( \mu, \mu_1, \mu_2, \ldots \) be probability measures on a measurable space \( S \). Let \( \nu \) be a finite measure on \( S \) such that \( \mu \ll \nu \) and \( \mu_n \ll \nu \) for all \( n \). Such \( \nu \) always exists, e.g., let \( \nu = \mu + \sum_n \frac{\mu_n}{2^n} \). Let \( f = d\mu/d\nu \) and \( f_n = d\mu_n/d\nu \). Then \( f, f_n \in L^1(\nu) \); \( \mu_n \to \mu \) in total variation iff \( f_n \to f \) in \( L^1(\nu) \); and \( \mu_n \to \mu \) strongly iff \( f_n \to f \) weakly in \( L^1(\nu) \), i.e., for any \( g \in L^\infty \), \( \int f_n g d\nu \to \int g d\nu \).

We now introduce a new concept: uniformly integrability, which plays an important role in the theory of martingales. To motivate the definition, we observe that if \( \zeta \in L^1 \), then by dominated convergence theorem, \( \mathbb{E}[1_{|\zeta| \geq R}] \to 0 \) as \( R \to \infty \).

**Definition.** A family of random variables \( \zeta_t, t \in T \), is called uniformly integrable, if

\[
\lim_{R \to \infty} \sup_{t \in T} \mathbb{E}[1_{|\zeta_t| \geq R}] = 0.
\]

The previous observation shows that any finite set of integrable random variables is uniformly integrable. The uniformly integrability depends only on the distributions of the random variables, and is stronger than the tightness of the distributions.

**Exercise.** For \( t \in T \), let \( \zeta_t \) be a random variable with distribution \( \mu_t \), and let \( p_{t,n} = \mathbb{P}[|\zeta_t| \geq n] \). Prove that \( \zeta_t, t \in T \), is uniformly integrable iff \( \sum_n p_{t,n} \) converges uniformly in \( t \in T \), which then implies that the family \( \mu_t, t \in T \), is tight.

**Exercise.** Prove that a sequence \( \zeta_1, \zeta_2, \ldots \in L^1 \) is uniformly integrable iff

\[
\lim_{R \to \infty} \limsup_{n \to \infty} \int_{\{|\zeta_n| \geq R\}} |\zeta_n| d\mathbb{P} = 0.
\]

**Lemma.** If for some \( p > 1 \), \( \{\zeta_t : t \in T\} \) is \( L^p \)-bounded, i.e., there is \( C < \infty \) such that \( \|\zeta_t\|_p \leq C \) for all \( t \in T \), then \( \zeta_t, t \in T, \) is uniformly integrable.

**Proof.** To see this, note that

\[
\int_{\{|\zeta_t| \geq R\}} |\zeta_t| d\mathbb{P} \leq \int_{\{|\zeta_t| \geq R\}} (|\zeta_t|/R)^{p-1} |\zeta_t| d\mathbb{P} \leq R^{1-p} \mathbb{E}|\zeta_t|^p = R^{1-p} \|\zeta_t\|_p^p \leq R^{1-p} C^p.
\]
The lemma does not hold for \( p = 1 \). For example, if \( \zeta_n = n1_{[0,1/n]} \), \( n \in \mathbb{N} \), are defined on \( ([0,1], \lambda) \), then \( \|\zeta_n\|_1 = 1 \) for all \( n \), but for any \( R > 0 \), \( \mathbb{E}[1_{\zeta_n \geq R\zeta_n}] = 1 \) if \( n \geq R \).

**Lemma 3.10.** The random variables \( \zeta_t, t \in T \), are uniformly integrable iff they are \( L^1 \)-bounded, and

\[
\lim_{\mathbb{P}A \to 0} \sup_{t \in T} \mathbb{E}[1_A |\zeta_t|] \to 0. \tag{3.2}
\]

**Proof.** Suppose \( \zeta_t, t \in T \), are uniformly integrable. Then

\[
\mathbb{E}[1_A |\zeta_t|] \leq R\mathbb{P}A + \mathbb{E}[1_{|\zeta_t| \geq R}|\zeta_t|].
\]

For any \( \varepsilon > 0 \), we may choose \( R > 0 \) such that \( \mathbb{E}[1_{|\zeta_t| \geq R}|\zeta_t|] < \varepsilon/2 \) for all \( t \in T \). Thus, if \( \mathbb{P}A < \varepsilon/(2R) \), then \( \mathbb{E}[1_A |\zeta_t|] < \varepsilon \) for all \( t \in T \). To get the \( L^1 \)-boundedness, we take \( A = \Omega \) and take \( R \) to be sufficiently big in the displayed formula.

Suppose now \( \zeta_t, t \in T \), are \( L^1 \)-bounded, and (3.2) holds. By Chebyshev’s inequality we get

\[
\mathbb{P}\{|\zeta_t| \geq R\} \leq \frac{1}{R} \sup_{t \in T} \|\zeta_t\|_1 \to 0, \quad R \to \infty,
\]

which together with (3.2) implies the uniformly integrability. \( \square \)

**Exercise.** Let \( \zeta_s, s \in S \), and \( \eta_t, t \in T \), be two uniformly integrable families of random variables. Then \( |\zeta_s| + |\eta_t|, (s,t) \in S \times T \), are also uniformly integrable.

**Proposition 3.12.** Fix \( p > 0 \). Suppose \( \zeta_1, \zeta_2, \ldots \in L^p \) are such that \( |\zeta_n|^p, n \in \mathbb{N} \), are uniformly integrable. Suppose \( \zeta_n \overset{p}{\to} \zeta \). Then \( \zeta_n \to \zeta \) in \( L^p \).

**Proof.** By Fatou’s lemma and the \( L^1 \)-boundedness of \( |\zeta_n|^p \) (by Lemma 3.10), we have

\[
\mathbb{E}|\zeta|^p \leq \liminf_n \mathbb{E}|\zeta_n|^p < \infty.
\]

So \( \zeta \in L^p \). Since \( |\zeta_n - \zeta|^p \leq 2^p(|\zeta_n|^p + |\zeta|^p) \), by the exercise above, \( |\zeta_n - \zeta|^p, n \in \mathbb{N} \), are also uniformly integrable. Fix \( \varepsilon > 0 \). Then

\[
\mathbb{E}[|\zeta_n - \zeta|^p] \leq \varepsilon^p + \mathbb{E}[1_{|\zeta_n - \zeta| \geq \varepsilon} |\zeta_n - \zeta|^p].
\]

Since \( \zeta_n \overset{p}{\to} \zeta \), as \( n \to \infty \), \( \mathbb{P}\{|\zeta_n - \zeta| \geq \varepsilon\} \to 0 \), which implies \( \mathbb{E}[1_{|\zeta_n - \zeta| \geq \varepsilon} |\zeta_n - \zeta|^p] \to 0 \) by Lemma 3.10. Sending \( n \to \infty \), we get \( \limsup_n \mathbb{E}[|\zeta_n - \zeta|^p] \leq \varepsilon^p \). Since this holds for any \( \varepsilon > 0 \), we get \( \mathbb{E}[|\zeta_n - \zeta|^p] \to 0 \). So \( \zeta_n \to \zeta \) in \( L^p \). \( \square \)

**Theorem 3.23** (strong law of large numbers). Let \( \zeta, \zeta_1, \zeta_2, \ldots \) be i.i.d. random variables with \( \mathbb{E}|\zeta| < \infty \). Let \( S_n = \sum_{k=1}^n \zeta_k \). Then a.s. \( \frac{1}{n} S_n \to \mathbb{E}\zeta \).

We are not going to prove the theorem following the approach of the textbook (Proposition 3.14, Lemma 3.15, Lemma 3.16, Theorem 3.17, Theorem 3.18, Lemma 3.19, Lemma 3.20, Lemma 3.21, Corollary 3.22). Instead, we give elementary proofs of some weaker results, and postpone the proof of Theorem 3.23 to the chapter of martingales.
**Theorem** (weak law of large numbers for $L^2$). In the setup of Theorem 3.23, if $\zeta \in L^2$, then $\frac{1}{n}S_n \xrightarrow{p} E\zeta$.

*Proof.* By subtracting $E\zeta$ from $\zeta$, we may assume that $E\zeta = 0$. Since $\zeta_1, \zeta_2, \ldots$ are independent,

$$E\left[\frac{1}{n} \sum_{j=1}^{n} \zeta_j^2\right] = \frac{1}{n^2} \text{var} \left( \sum_{j=1}^{n} \zeta_j \right) = \frac{1}{n^2} \sum_{j=1}^{n} \text{var} (\zeta_j) = \frac{1}{n} \text{var} (\zeta).$$

By Chebyshev inequality, for any $\varepsilon > 0$,

$$P\left[ \left| \frac{1}{n} \sum_{j=1}^{n} \zeta_j \right| \geq \varepsilon \right] \leq \frac{1}{\varepsilon^2} E\left[ \left| \frac{1}{n} \sum_{j=1}^{n} \zeta_j \right|^2 \right] \leq \frac{1}{n} \text{var} (\zeta) \to 0,$$

as $n \to \infty$. So $\frac{1}{n} \sum_{j=1}^{n} \zeta_j \xrightarrow{p} 0$. 

**Theorem** (strong law of large numbers for $L^4$). Theorem 3.23 holds if $\zeta \in L^4$.

*Proof.* We again assume that $E\zeta = 0$. We have

$$E\left[ \left( \frac{1}{n} S_n \right)^4 \right] = \frac{1}{n^4} \sum_{1 \leq j_1, j_2, j_3, j_4 \leq n} E[\zeta_{j_1} \zeta_{j_2} \zeta_{j_3} \zeta_{j_4}].$$

If for some $s \in \{1, 2, 3, 4\}$, $j_s \not\in \{j_t : t \neq s\}$, then by independence of $\zeta_1, \zeta_2, \ldots$ and that $E\zeta_{j_s} = 0$, we get

$$E[\zeta_{j_1} \zeta_{j_2} \zeta_{j_3} \zeta_{j_4}] = E\zeta_{j_s} E\prod_{t \neq s} \zeta_{j_t} = 0.$$

Thus,

$$E\left[ \left( \frac{1}{n} \sum_{j=1}^{n} \zeta_j \right)^4 \right] = \frac{1}{n^4} \sum_{j=1}^{n} E\zeta_j^4 + \frac{12}{n^4} \sum_{1 \leq j < k \leq n} E\zeta_j^2 \zeta_k^2 = \frac{1}{n^3} E\zeta^4 + \frac{6(n-1)}{n^3} (E\zeta^2)^2 \leq \frac{6}{n^2} E\zeta^4.$$

In the last inequality, we used $(E\zeta^2)^2 \leq E\zeta^4$. So for any $\varepsilon > 0$, by Chebyshev inequality,

$$P\left[ \left| \frac{1}{n} S_n \right| \geq \varepsilon \right] \leq \frac{1}{\varepsilon^4} E\left[ \left( \frac{1}{n} S_n \right)^4 \right] \leq \frac{6}{n^2} \frac{E\zeta^4}{\varepsilon^4}.$$

Since $\sum_n \frac{E\zeta^4}{n^2 \varepsilon^4} < \infty$, by Borel-Cantelli lemma, a.s. there is a random $N$ such that for $n > N$, $\left| \frac{1}{n} S_n \right| < \varepsilon$. This implies that $\frac{1}{n} \sum_{j=1}^{n} \zeta_j \to 0$ a.s. \qed

**Exercise.** Problems 4, 5, 6, 8, 11, of Exercises of Chapter 3.
4 Characteristic Functions and Classical Limit Theorems

Suppose $\zeta$ is a random vector in $\mathbb{R}^d$ with distribution $\mu$, the associated characteristic function $\widehat{\mu}$ is given by

$$\widehat{\mu}(t) = \int e^{itx} \mu(dx) = \mathbb{E}e^{it\zeta}, \quad t \in \mathbb{R}^d,$$

where $tx$ denotes the inner product $t_1x_1 + \cdots + t_dx_d$. The function $x \mapsto e^{itx}$ is integrable because $|e^{itx}| = 1$. In the language of Analysis, $\widehat{\mu}$ is the Fourier transform of $\mu$. If $\mu$ is a distribution on $\mathbb{R}^d_+$, i.e., $\mu|_{\mathbb{R}^d_+} = 1$, then the Laplace transform $\tilde{\mu}$ is defined by

$$\tilde{\mu}(t) = \int e^{-tx} \mu(dx) = \mathbb{E}e^{-t\zeta}, \quad t \in \mathbb{R}^d_+.$$

The function $x \mapsto e^{-tx}$ is integrable because $0 < e^{-tx} \leq 1$ as $tx \geq 0$. Finally, for a distribution $\mu$ on $\mathbb{Z}_+ = \{0, 1, 2, \ldots\}$, the generating function $\psi$ is defined by

$$\psi(s) = \sum_{n=0}^{\infty} s^n \mathbb{P}\{\zeta = n\} = \mathbb{E}s^\zeta, \quad s \in [0, 1].$$

Formally, $\tilde{\mu}(u) = \widehat{\mu}(iu)$ and $\tilde{\mu}(t) = \mu(-it)$, $\tilde{\mu}(u) = \psi(e^{-u})$ and $\psi(s) = \tilde{\mu}(-\log s)$. We will focus on characteristic functions. Many results also apply to Laplace transforms and generating functions with similar proofs.

We first list some simple properties of characteristic functions.

(i) If $\phi$ is the characteristic function for $\zeta$, then for any $a \in \mathbb{R}$ and $b \in \mathbb{R}^d$, the characteristic function for $a\zeta + b$ is $e^{ibt}\phi(at)$.

(ii) If $\phi_1, \ldots, \phi_n$ are characteristic functions for independent $\zeta_1, \ldots, \zeta_n$, then the characteristic function for $\zeta_1 + \cdots + \zeta_n$ is $\prod_{j=1}^n \phi_j(t)$. We used the fact that $e^{it\zeta_1}, \ldots, e^{it\zeta_n}$ are independent. Thus, if $\zeta_1, \ldots, \zeta_n$ are i.i.d. with characteristic function $\phi$, and $S_n = \sum_{k=1}^n \zeta_k$, then the characteristic function for $\frac{1}{n} S_n$ is $\phi(t/n)^n$.

(iii) For any characteristic function $\phi$, $\phi(0) = 1$ and for any $t \in \mathbb{R}^d$, $|\phi(t)| \leq 1$ and $\phi(-t) = \overline{\phi(t)}$, where the bar stands for the complex conjugate. Here we use the inequality $|\mathbb{E}f| \leq \mathbb{E}|f|$ for complex random variable $f$ and the equality $e^{itx} = e^{-itx}$.

(iv) $\phi$ is uniformly integrable. Here we use that $|e^{it_1x} - e^{it_2x}| = |e^{it_1(t_2-x)} - 1| \leq 2 \wedge (|t-s||x|)$ and dominated convergence theorem.

(v) If $\mu_n$ converges weakly to $\mu$ with associated characteristic functions $\phi_n$ and $\phi$, then for any $t \in \mathbb{R}^d$, $\phi_n(t) \to \phi(t)$. Here we used the fact that, for any $t \in \mathbb{R}^d$, $x \mapsto e^{itx}$ is a bounded and continuous.
(vi) In the case $d = 1$, if $\mathbb{E}|\zeta|^n < \infty$ for some $n \in \mathbb{N}$, then $\phi$ is $n$-times continuously differentiable, $\phi^{(n)}$ is bounded and uniformly continuous, and $\phi^{(n)}(0) = i^n \mathbb{E} \zeta^n$. To see this is true, we may formally differentiate \[ w.r.t. t \] and get $\phi'(t) = \mathbb{E}[ixe^{itx}]$. If we continue differentiation, then we get $\phi^{(k)}(t) = \mathbb{E}[(ix)^k e^{itx}]$ for all $k \in \mathbb{N}$. In general, these equalities do not hold. In fact, $(ix)^k e^{itx}$ may not be integrable. However, if $\mathbb{E}|\zeta|^n < \infty$ for some $n \in \mathbb{N}$, then for any $0 \leq k \leq n$ and $t \in \mathbb{R}^d$, $(i\zeta)^k e^{it\zeta}$ is integrable, and we may define $\phi_k(t) = \mathbb{E}[(i\zeta)^k e^{it\zeta}]$, $0 \leq k \leq n$. Here $\phi[0] = \phi$. Since $|(ix)^k e^{itx} - (ix)^k e^{isx}| \leq |x|^k(2 \wedge |s - t||x|)$, by DCT, we see that $\phi_k$ is uniformly continuous for each $0 \leq k \leq n$. By Fubini Theorem, for $1 \leq k \leq n$ and $a < b \in \mathbb{R}$, $\int_a^b \phi_k(t) = \mathbb{E}[e^{i(\zeta - t\zeta)^k}]$. Taking $t = 0$, we get $\phi_k(0) = \mathbb{E}[(i\zeta)^k] = i^k \mathbb{E}[\zeta^k]$.

The following theorem is important for us.

**Theorem 4.3.** For probability measures $\mu, \mu_1, \mu_2, \ldots$ on $\mathbb{R}^d$, $\mu_n \xrightarrow{w} \mu$ iff $\hat{\mu}_n \to \hat{\mu}$ pointwise iff $\hat{\mu}_n \to \hat{\mu}$ uniformly on every bounded set.

That $\mu_n \xrightarrow{w} \mu$ implies that $\hat{\mu}_n \to \hat{\mu}$ pointwise is Property (v) above. We postpone the proof to the end of this chapter. This theorem in particular implies that $\hat{\mu}$ determines $\mu$.

**Example.** (i) If $\mu$ is the degeneracy distribution $\delta_{x_0}$, then $\hat{\mu}(t) = e^{itx_0}$.

(ii) If $\mu$ is the Bernoulli distribution $\text{B}(p)$, then $\hat{\mu}(t) = pe^{it-1} + (1-p)e^{it0} = 1 - p + pe^{it}$.

(iii) If $\mu$ is the binomial distribution $\text{B}(n,p)$, since it is the $n$-th convolution power of the Bernoulli distribution $\text{B}(p)$, we get $\hat{\mu}(t) = (1 - p + pe^{it})^n$.

(iv) If $\mu$ is the geometric distribution Geom$(p)$, then

$$\hat{\mu}(t) = \sum_{k=1}^{\infty} (1-p)^{k-1}pe^{itk} = \frac{pe^{it}}{1-(1-p)e^{it}}.$$  

(v) If $\mu$ is the Poisson distribution $\text{Pois}(\lambda)$, then

$$\hat{\mu}(t) = \sum_{k=0}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} e^{itk} = e^{\lambda e^{it} - \lambda}.$$  

(vi) If $\mu$ is the uniform distribution $\text{U}[a,b]$, then

$$\hat{\mu}(t) = \frac{1}{b-a} \int_a^b e^{itx} dx = \frac{e^{itb} - e^{ita}}{itb - ita}.$$  

(vii) If $\mu$ is the exponential distribution $\text{Exp}(\lambda)$, then

$$\hat{\mu}(t) = \int_0^\infty \lambda e^{-\lambda x} e^{itx} dx = \frac{\lambda}{\lambda - it}.$$  

53
(viii) If $\mu$ is the normal distribution $N(\alpha, \sigma^2)$, then
\[
\hat{\mu}(t) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi} \sigma} e^{-\frac{(x-\alpha)^2}{2\sigma^2}} e^{itx} \, dx = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}} e^{it(\alpha+\sigma y)} \, dy
\]
\[
= e^{-\frac{t^2}{2} + i\alpha t} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2} + iy\sigma t} \, dy = e^{-\frac{t^2}{2} + i\alpha t}.
\]

Here the last equality follows from contour integral in complex analysis. The statement holds true even if $\sigma = 0$. When $\mu$ is $N(0, 1)$, the characteristic function is $e^{-\frac{t^2}{2}}$.

We now study some applications of Theorem 4.3.

**Theorem** (weak law of large numbers for $L^1$). Let $\zeta, \zeta_1, \zeta_2, \ldots$ be an i.i.d. sequence random variables in $L^1$. Let $S_n = \sum_{j=1}^{n} \zeta_j$. Then $\frac{1}{n} S_n \xrightarrow{P} \mathbb{E}\zeta$.

**Proof.** Let $\phi$ be the characteristic function for $\zeta$. Since $\zeta \in L^1$, $\phi \in C^1$, $\phi(0) = 1$ and $\phi'(0) = i\mathbb{E}\zeta$. The characteristic function for $\frac{1}{n} S_n$ is $\phi(t/n)^n = \exp(n \log \phi(t/n))$, which tends to $\exp(t \frac{d}{dt} \log \phi(0)) = e^{it\phi'(0)/\phi(0)} = e^{it\mathbb{E}\zeta}$ as $n \to \infty$. Since $e^{it\mathbb{E}\zeta}$ is the characteristic function for $\delta_{\mathbb{E}\zeta}$, by Theorem 3.4, $\text{Law} \left( \frac{1}{n} S_n \right) \to \delta_{\mathbb{E}\zeta}$. So $\frac{1}{n} S_n \xrightarrow{P} \mathbb{E}\zeta$. \hfill \Box

**Proposition 4.9** (central limit theorem). Let $\zeta, \zeta_1, \zeta_2, \ldots$ be i.i.d. random variables in $L^2$ with $\mathbb{E}\zeta = 0$ and $\mathbb{E}\zeta^2 = 1$. Let $S_n = \sum_{j=1}^{n} \zeta_j$. Then $\text{Law}(n^{-1/2} S_n) \xrightarrow{w} N(0, 1)$.

**Proof.** Let $\phi$ be the characteristic function for $\zeta$. Since $\zeta \in L^2$, we have $\phi \in C^2$, $\phi(0) = 1$, $\phi'(0) = i\mathbb{E}\zeta = 0$, and $\phi''(0) = -\mathbb{E}\zeta^2 = -1$. The characteristic function for $n^{-1/2} S_n$ is $\phi(n^{-1/2} t)^n = \exp(n \log \phi(t/n^{1/2}))$. By Taylor theorem, as $n \to \infty$,
\[
\phi\left( \frac{t}{\sqrt{n}} \right) = 1 - \frac{t^2}{2n} + o\left( \frac{1}{n} \right),
\]
which implies that
\[
\log \phi\left( \frac{t}{\sqrt{n}} \right) = -\frac{t^2}{2n} + o\left( \frac{1}{n} \right).
\]
So we have
\[
\phi(n^{-1/2} t)^n = \exp(n \log \phi(t/n^{1/2})) \to e^{-\frac{t^2}{2}}, \quad \text{as } n \to \infty.
\]
Since $e^{-\frac{t^2}{2}}$ is the characteristic function for $N(0, 1)$. The proof is complete by Theorem 4.3. \hfill \Box

**Theorem** (Poisson limit theorem). For any $\lambda > 0$, as $n \to \infty$, the binomial distributions $B(n, \lambda/n)$ tend weakly to the Poisson distribution $\text{Pois}(\lambda)$.

**Proof.** The characteristic function for $B(n, \lambda/n)$ is
\[
\phi_n = \left(1 - \lambda/n + \lambda/ne^{it} \right)^n \to e^{\lambda e^{it} - \lambda}, \quad \text{as } n \to \infty.
\]
Since $e^{\lambda e^{it} - \lambda}$ is the characteristic function for $\text{Pois}(\lambda)$, the proof is done. \hfill \Box
The rest of this chapter is devoted to the proof of Theorem 4.3. Recall the definition of tightness: a family of probability measures \( \mu_t, t \in T \), on a topological space \( S \) is tight if for any \( \varepsilon > 0 \), there is a compact set \( K \subset S \) such that \( \mu_t(K^c) < \varepsilon \) for all \( t \in T \). When \( S = \mathbb{R}^d \), this is equivalent to \( \lim_{r \to \infty} \sup_{t \in T} \mu_t \{ x : |x| \geq r \} = 0 \). If, in addition, \( T = \mathbb{N} \), this is further equivalent to \( \lim_{r \to \infty} \limsup_n \mu_n \{ x : |x| \geq r \} = 0 \).

**Lemma 3.8.** A weakly convergent sequence of probability measures on \( \mathbb{R}^d \) is tight.

This is a special case of Prokhorov Theorem. But we can now give a direct proof.

**Proof.** For any \( r > 1 \), we define a bounded continuous function \( f_r \) on \( \mathbb{R}^d \) by \( f_r(x) = 0 \) if \( |x| \leq r - 1 \), \( f_r(x) = 1 \) if \( |x| \geq r \), and \( f_r(x) = |x| - (r - 1) \) if \( r - 1 \leq |x| \leq r \). Then

\[
\limsup_n \mu_n \{ x : |x| \geq r \} = \limsup_n \mu_n f_r = \mu f_r \leq \mu \{ x : |x| \geq r - 1 \}.
\]

Here the RHS tends to 0 as \( r \to \infty \). So \( \lim_{r \to \infty} \limsup_n \mu_n \{ x : |x| \geq r \} = 0 \).

**Lemma 3.9.** Let \( \zeta_1, \zeta_2, \ldots \) be random vectors in \( \mathbb{R}^d \) with laws \( \mu_1, \mu_2, \ldots \). Then \( \{ \mu_n \} \) is tight iff \( c_n \zeta_n \xrightarrow{P} 0 \) for any constants \( c_1, c_2, \cdots \geq 0 \) with \( c_n \to 0 \).

**Proof.** First assume that \( \{ \mu_n \} \) is tight. Let \( c_n \to 0 \). Fix any \( r, \varepsilon > 0 \). We note that \( |c_n r| \leq \varepsilon \) for all but finitely many \( n \). So \( |c_n \zeta_n| > \varepsilon \) implies \( |\zeta_n| > r \) for all but finitely many \( n \). So we get

\[
\limsup \mathbb{P}\{ |c_n \zeta_n| > \varepsilon \} \leq \limsup \mathbb{P}\{ |\zeta_n| > r \}.
\]

Here the RHS tends to 0 as \( r \to \infty \), and the LHS does not depend on \( r \). So \( \limsup \mathbb{P}\{ |c_n \zeta_n| > \varepsilon \} = 0 \), which implies that \( \lim \mathbb{P}\{ |c_n \zeta_n| > \varepsilon \} = 0 \). Since this holds for any \( \varepsilon > 0 \), we get \( c_n \zeta_n \xrightarrow{P} 0 \).

If \( \{ \mu_n \} \) is not tight. Then we can find \( \varepsilon_0 > 0 \) and a subsequence \( \{ \mu_{n_k} \} \) such that \( \mathbb{P}\{ |\zeta_{n_k}| \geq k \} \geq \varepsilon_0 \) for all \( k \). We may then find \( c_1, c_2, \cdots \geq 0 \) with \( c_n \to 0 \) such that \( c_{n_k} = \frac{1}{k} \). Then \( \mathbb{P}\{ |c_{n_k} \zeta_{n_k}| \geq 1 \} \geq \varepsilon_0 \) for all \( k \), which implies that \( c_n \zeta_n \) does not converge to 0 in probability.

**Lemma 4.1.** For any probability measure \( \mu \) on \( \mathbb{R} \) and \( r > 0 \), we have

\[
\mu \{ x : |x| \geq r \} \leq \frac{r}{2} \int_{-2/r}^{2/r} (1 - \tilde{\mu}(t))dt; \tag{4.2}
\]

**Proof.** Let \( c > 0 \). By Fubini Theorem and straightforward calculation,

\[
\int_{-c}^{c} (1 - \tilde{\mu}(t))dt = \int_{-c}^{c} \int_{\mathbb{R}} (1 - e^{itx})\mu(dx)dt = \int_{\mathbb{R}} \int_{-c}^{c} (1 - e^{itx})dt\mu(dx)
\]

\[
= \int_{\mathbb{R}} \left( t - \frac{e^{itx}}{itx} \right) \bigg|_{t = -c}^{t = c} \mu(dx) = 2c \int_{\mathbb{R}} (1 - \frac{\sin(cx)}{cx}) \mu(dx) \geq c\mu \{ x : |cx| \geq 2 \},
\]

where the last step follows from \( \sin x \leq 1 \leq x/2 \) for \( x \geq 2 \). Letting \( c = \frac{2}{r} \), we get (4.2).
Remark. For \(1 \leq k \leq d\), let \(e_k \in \mathbb{R}^d\) be the vector whose \(k\)-th coordinate is 1 and other coordinates are 0; let \(\pi_k\) be the projection \(x \mapsto x_k = e_k x\) from \(\mathbb{R}^d\) to \(\mathbb{R}\). For a probability measure \(\mu\) on \(\mathbb{R}^d\), and \(1 \leq k \leq d\), let \(\mu^k = (\pi_k)_* \mu\). Then we get

\[
\hat{\mu}^k(t) = \int_{\mathbb{R}} e^{itx} \mu^k(dx) = \int_{\mathbb{R}^d} e^{itx_k} \mu(dx) = \int_{\mathbb{R}^n} e^{i(t_e_x)k} \mu(dx) = \hat{\mu}(t e_k), \quad 1 \leq k \leq d.
\]

By Lemma 4.1, we have

\[
\mu(\mathbb{R}^d \setminus [-\delta, \delta]^d) \leq \sum_{k=1}^{n} \mu\{x \in \mathbb{R}^d : |x_k| \geq \delta\} = \sum_{k=1}^{d} \mu_k \{x \in \mathbb{R} : |x| \geq \delta\}
\]

\[
\leq \sum_{k=1}^{d} \frac{\delta}{2} \int_{-\delta}^{\delta} (1 - \hat{\mu}^k(t)) dt = \sum_{k=1}^{d} \frac{\delta}{2} \int_{-1}^{1} (1 - \hat{\mu}(t e_k)) dt.
\]

(4.3)

Lemma 4.2. A family \(\{\mu_\alpha\}\) of probability measures on \(\mathbb{R}^d\) is tight iff \(\{\hat{\mu}_\alpha\}\) is equicontinuous at 0, and then \(\{\hat{\mu}_\alpha\}\) is uniformly equicontinuous on \(\mathbb{R}^d\).

Proof. Note that \(\{\mu_\alpha\}\) is tight iff \(\mu_\alpha(\mathbb{R}^d \setminus [-r, r]^d) \to 0\) as \(r \to \infty\), uniformly in \(\alpha\). First, suppose \(\{\hat{\mu}_\alpha\}\) is equicontinuous at 0. Then for each \(1 \leq k \leq d\), \(\frac{\delta}{2} \int_{-1}^{1} (1 - \hat{\mu}_\alpha(t e_k)) dt \to 0\) as \(r \to \infty\), uniformly in \(\alpha\). By (4.3) we see that \(\{\mu_\alpha\}\) is tight.

Next, suppose \(\{\mu_\alpha\}\) is tight. Let \(\xi_\alpha\) be a random vector with law \(\mu_\alpha\). We compute that for \(s, t \in \mathbb{R}^d\),

\[
|\hat{\mu}_{\alpha}(s) - \hat{\mu}_{\alpha}(t)| = E|e^{i(s-t)\xi_\alpha} - 1| \leq E|\|(s-t)\xi_\alpha| \wedge 2|.
\]

By Lemma 3.9, for any sequence \((\alpha_n)\) of indices and any two sequences \((s_n)\) and \((t_n)\) in \(\mathbb{R}^d\) with \(|s_n - t_n| \to 0\), we get \((s_n - t_n)\xi_{\alpha_n} \xrightarrow{p} 0\), which implies by DCT that \(E|\|(s_n - t_n)\xi_{\alpha_n}| \wedge 2| \to 0\), and so by the above formula, \(|\hat{\mu}_{\alpha_n}(s_n) - \hat{\mu}_{\alpha_n}(t_n)| \to 0\). This shows that \(\{\hat{\mu}_\alpha\}\) is uniformly equicontinuous on \(\mathbb{R}^d\), and in particular is equicontinuous at 0.

We also need the following approximation lemma from Analysis.

Lemma 4.4 (Stone-Weierstrass approximation). Every continuous function \(f : \mathbb{R}^d \to \mathbb{R}\) with period \(2\pi\) in each coordinate admits a uniform approximation by linear combinations of \(e^{ikx}\), \(k \in \mathbb{Z}^d\).

Proof. We first consider the case \(d = 1\). In this case \(f\) has a Fourier series \(\sum_{n \in \mathbb{Z}} a_n e^{inx}\), where \(a_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x)e^{-inx} dx\). The truncated series \(\sum_{n=-N}^{N} a_n e^{inx}\) is a linear combinations of \(e^{inx}\), \(n \in \mathbb{Z}\), but may not converge uniformly to \(f\).

The approximation sequence is constructed as follows. Let \(N \in \mathbb{N}\). Let \(h_N(x)\) be the sum of the finite geometric series

\[
h_N(x) = e^{i(1-N)x/2} + e^{i(3-N)x/2} + \cdots + e^{i(N-3)x/2} + e^{i(N-1)x/2} = e^{i(1-N)x/2} \sum_{k=0}^{N-1} e^{ikx}.
\]

56
It has ratio $e^{ix}$, the leading term $e^{i(1-N)x/2}$ and the ending term $e^{i(N-1)x/2}$. We observe that $e^{ix/2}h_N(x) - e^{-ix/2}h_N(x) = e^{iN/2} - e^{-iN/2}$, and so $h_N(x) = \frac{e^{iN/2} - e^{-iN/2}}{e^{ix/2} - e^{-ix/2}} = \frac{\sin(Nx/2)}{\sin(x/2)}$.

Calculating $h_N(x)^2$ using the series expression, we get

$$\frac{\sin^2(Nx/2)}{\sin^2(x/2)} = e^{i(1-N)x} \left( \sum_{n=0}^{N-1} e^{inx} \right) \left( \sum_{m=0}^{N-1} e^{imx} \right) = e^{i(1-N)x} \sum_{k=0}^{2N-2} \sum_{0 \leq n,m \leq N-1, n+m=k} e^{ikx}$$

$$= e^{i(1-N)x} \sum_{k=0}^{2N-2} (N - |N - 1 - k|)e^{ikx} = \sum_{j=1-N}^{N-1} (N - |j|)e^{ijx}.$$

Let $b_n^{(N)} = (1 - \frac{|n|}{N})$. Then $\sum_{n=1}^{N-1} b_n^{(N)} e^{inx} = \frac{\sin^2(Nx/2)}{N \sin^2(x/2)}$. We define $g_N(x) = \frac{\sin^2(Nx/2)}{N \sin^2(x/2)}$. Then $g_N \geq 0$, and $\frac{1}{2\pi} \int_{-\pi}^{\pi} g_N(x)dx = b_0^{(N)} = 1$.

Let

$$f_N(x) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x-y)g_N(y)dy = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(y)g_N(x-y)dy = \sum_{n} \frac{1}{2\pi} \int_{-\pi}^{\pi} f(y)b_n^{(N)} e^{inx}dy = \sum_{n} a_n b_n^{(N)} e^{inx}.$$  

So $f_N$ is a linear combination of $e^{ikx}$, $k \in \mathbb{Z}$. To see that $f_N \to f$ uniformly, we compute

$$|f_N(x) - f(x)| = \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} (f(x-y) - f(x))g_N(y)dy \right| \leq \frac{1}{2\pi} \int_{-\pi}^{\pi} |f(x-y) - f(x)|g_N(y)dy$$

$$= \frac{1}{2\pi} \int_{-\delta}^{\delta} |f(x-y) - f(x)|g_N(y)dy + \frac{1}{2\pi} \int_{[\pi, \pi] \setminus [-\delta, \delta]} |f(x-y) - f(x)|g_N(y)dy$$

$$\leq \sup_{|x-z| \leq \delta} |f(x) - f(z)| + 2\|f\| \cdot \frac{1}{2\pi} \int_{[\pi, \pi] \setminus [-\delta, \delta]} g_N(y)dy. \quad (4.4)$$

We note that for any fixed $\delta \in (0, \pi)$, $\frac{1}{2\pi} \int_{[\pi, \pi] \setminus [-\delta, \delta]} g_N(y)dy \to 0$ as $N \to \infty$ because

$$\sup_{y \in [\pi, \pi] \setminus [-\delta, \delta]} g_N(y) \leq \frac{1}{N \sin^2(\delta/2)}.$$  

Given any $\varepsilon > 0$, we may first choose $\delta \in (0, \pi)$ such that $\sup_{|x-z| \leq \delta} |f(x) - f(z)| < \frac{\varepsilon}{2}$, and then choose $N_0$ such that for $N > N_0$, the second term of (4.4) is also less than $\frac{\varepsilon}{2}$.

For general dimension $d$, we let $g_N^{(d)}(x) = \prod_{k=1}^{d} g_N(x_k)$. Then $g_N^{(d)} \geq 0$, is a linear combination of $e^{ikx}$, $k \in \mathbb{Z}^d$, and satisfies $\frac{1}{(2\pi)^d} \int_{[-\pi, \pi]^d} g_N^{(d)}(y)dy = 1$. Let

$$f_N(x) = \frac{1}{(2\pi)^d} \int_{[-\pi, \pi]^d} f(x-y)g_N^{(d)}(y)dy = \frac{1}{(2\pi)^d} \int_{[-\pi, \pi]^d} f(y)g_N^{(d)}(x-y)dy.$$  

57
Then each $f_N$ is a linear combination of $e^{ikx}$, $k \in \mathbb{Z}^d$. A similar computation with $[-\delta, \delta]^d$ and $[-\pi, \pi]^d$ in place of $[-\delta, \delta]$ and $[-\pi, \pi]$ shows that

$$|f_N(x) - f(x)| \leq \sup_{\max_k |x_k - z_k| \leq \delta} |f(x) - f(z)| + \frac{2\|f\|}{(2\pi)^d} \int_{[-\pi, \pi]^d \setminus [-\delta, \delta]^d} g^{(d)}_N(y)dy.$$  

To conclude that $f_n \to f$ uniformly, we need to show that for any $\delta \in (0, \pi)$,

$$\int_{[-\pi, \pi]^d \setminus [-\delta, \delta]^d} g^{(d)}_N(y)dy \to 0, \quad \text{as } N \to \infty. \quad (4.5)$$

Now we do not have $\sup_{y \in [-\pi, \pi]^d \setminus [-\delta, \delta]^d} g^{(d)}_N(y) \to 0$ as $N \to \infty$. However, if we let $U_k = \{x \in [-\pi, \pi]^d : |x_k| \geq \delta\}$, $1 \leq k \leq d$, then the LHS of $(4.5)$ is

$$\leq \sum_{k=1}^d \int_{U_k} g^{(d)}_N(y)dy = d\left( \int_{[-\pi, \pi]^d} g_N(y)dy \right)^{d-1} \cdot \int_{[-\pi, \pi] \setminus [-\delta, \delta]} g_N(y)dy \leq \frac{d(2\pi)^d}{N \sin^2(\delta/2)}.$$  

So we get $(4.5)$ and conclude the proof.\hfill \Box

**Proof of Theorem 4.3.** If $\mu_n \xrightarrow{w} \mu$, then for each $t \to \mathbb{R}^d$, since $x \mapsto e^{itx}$ is bounded and continuous on $\mathbb{R}^d$, we get $\hat{\mu}_n(t) \to \hat{\mu}(t)$. By Lemma 3.8, $\{\mu_n\}$ is tight. By Lemma 4.2, $\{\hat{\mu}_n\}$ is uniformly equicontinuous on $\mathbb{R}^d$. So $\hat{\mu}_n \to \hat{\mu}$ uniformly on every bounded set.

Suppose now $\hat{\mu}_n \to \hat{\mu}$ pointwise. By (4.3) we have

$$\limsup_n \mu_n(\mathbb{R}^d \setminus [-r, r]) \leq \limsup_n \frac{d}{2} \int_{-2/r}^{2/r} (1 - \hat{\mu}_n(te_k))dt = \frac{d}{2} \int_{-2/r}^{2/r} (1 - \hat{\mu}(te_k))dt,$$

where the equality follows from DCT. Since $\hat{\mu}$ is continuous at 0, the RHS tends to 0 as $r \to \infty$, which shows that $\{\mu_n\}$ is tight.

Given any $\varepsilon > 0$, we may then choose $r > 0$ so large such that $\mu_n\{|x| \geq r\} < \varepsilon$ for each $n$ and $\mu\{|x| \geq r\} < \varepsilon$. Now fix $f \in C_b(\mathbb{R}^d)$. We need to show that $\mu_n f \to \mu f$. By the definition of $\hat{\mu}_n$ and $\hat{\mu}$, we know this is true if $f$ is of the form $x \mapsto e^{ix \cdot t}$ for some $t \in \mathbb{R}^d$, or is a linear combination of such functions. Let $m = \|f\|$, the supremum norm of $f$. Let $h \in C(\mathbb{R}^d)$ be such that $0 \leq h \leq 1$, $h \equiv 1$ on $\{|x| \leq r\}$, and $h \equiv 0$ on $\mathbb{R}^d \setminus (-\pi r, \pi r)^d$. Then $\|hf\| \leq m$, $hf$ agrees with $f$ in $\{|x| \leq r\}$, and vanishes outside $(-\pi r, \pi r)^d$. So we may extend $hf$ from $(-\pi r, \pi r)^d$ to $\tilde{f} \in C(\mathbb{R}^d)$, which has period $2\pi r$ in each coordinate. Then $\tilde{f}$ agrees with $f$ on $\{|x| \leq r\}$, and $\|\tilde{f}\| = \|hf\| \leq m$. By Lemma 4.4 there exists some linear combination $g$ of $e^{ikx}$, $k \in \mathbb{Z}^d$, such that $\|\tilde{f} - g\| < \varepsilon$. By earlier discussion, $\mu_n g \to \mu g$. For any $n \in \mathbb{N}$,

$$|\mu_n f - \mu_n g| \leq \mu_n \{|x| \geq r\} \|f - \tilde{f}\| + \|\tilde{f} - g\| \leq 2m\varepsilon + \varepsilon,$$

and similarly for $\mu$. Thus,

$$|\mu_n f - \mu f| \leq |\mu_n f - \mu_n g| + 2(2m + 1)\varepsilon, \quad n \in \mathbb{N}.$$

Letting $n \to \infty$ and then $\varepsilon \to 0$, we get $\mu_n f \to \mu f$. Since $f \in C_b$ is arbitrary, we get $\mu_n \xrightarrow{w} \mu$.\hfill \Box

**Exercise.** Problems 6, 14 of Exercises of Chapter 4.
5 Conditioning and Disintegration

We now study conditioning. We still fix a probability space \((\Omega, \mathcal{A}, \mathbb{P})\). Suppose \(B \in \mathcal{A}\) is such that \(\mathbb{P}[B] > 0\). We may then define a conditional probability

\[
\mathbb{P}[A|B] = \frac{\mathbb{P}[A \cap B]}{\mathbb{P}[B]}, \quad A \in \mathcal{A}.
\]

It is easy to see that \(\mathbb{P}[\cdot|B]\) is a probability measure on \((\Omega, \mathcal{A})\). The expectation w.r.t. this probability measure is then given by

\[
\mathbb{E}[\zeta|B] = \frac{\mathbb{E}[1_B \zeta]}{\mathbb{P}[B]}.
\]

We want to extend the above concept and define conditional expectation \(\mathbb{E}[\cdot|F]\), where \(F\) is a sub-\(\sigma\)-algebra of \(\mathcal{A}\). To motivate the definition, we suppose \(B_1, \ldots, B_n\) is a measurable partition of \(\Omega\) such that \(\mathbb{P}[B_k] > 0\) for each \(1 \leq k \leq n\). They together generate a sub-\(\sigma\)-algebra \(F_B\), each element is a union of some \(B_k\)'s. Given an integrable random variable \(\zeta\), consider its conditional expectation given \(B_k\), we get \(n\) real values \(\mathbb{E}[\zeta|B_1], \ldots, \mathbb{E}[\zeta|B_n]\). We now define a new random variable \(\zeta_B\) on \(\Omega\) by

\[
\zeta_B = \sum_{k=1}^{n} \mathbb{E}[\zeta|B_k] 1_{B_k}.
\]

(5.1)

Then \(\zeta_B\) is \(F_B\)-measurable, and for any \(B_k\),

\[
\mathbb{E}[1_{B_k} \zeta_B] = \mathbb{E}[\zeta|B_k] \mathbb{P}[B_k] = \mathbb{E}[1_{B_k} \zeta].
\]

Since every \(A \in F_B\) is a disjoint union of some \(B_k\)'s, we get

\[
\mathbb{E}[1_A \zeta_B] = \mathbb{E}[1_A \zeta], \quad \forall A \in F_B
\]

(5.2)

On the other hand, suppose \(\zeta_B\) is an \(F_B\)-measurable random variable and satisfies (5.2). Then \(\zeta_B\) takes constant value on each \(B_k\), and so can be expressed as \(\sum_k c_k 1_{B_k}\) for some \(c_1, \ldots, c_n \in \mathbb{R}\). Taking \(A = B_k\) in (5.2), we get \(c_k \mathbb{P}[B_k] = \mathbb{E}[1_{B_k} \zeta]\), which implies that \(c_k = \mathbb{E}[\zeta|B_k]\). So \(\zeta_B\) is given by (5.1), and we can reveal \(\mathbb{E}[\zeta|B_k]\) for each \(k\) from \(\zeta_B\).

**Definition.** For a sub-\(\sigma\)-algebra \(F\) of \(A\) and \(\zeta \in L^1(\mathcal{A}, \mathbb{P})\), we use \(\mathbb{E}[\zeta|F]\) or \(\mathbb{E}^F \zeta\) to denote an element \(\eta \in L^1(F, \mathbb{P})\), which satisfies that

\[
\mathbb{E}[1_A \zeta] = \mathbb{E}[1_A \eta], \quad \forall A \in F.
\]

(5.3)

For \(A \in \mathcal{A}\), we define \(\mathbb{P}^F A = \mathbb{P}[A|F]\) as \(\mathbb{E}[1_A|F]\). If \(\eta\) is a random element, then we define \(\mathbb{E}[\zeta|\eta] = \mathbb{E}^\eta \zeta\) as \(\mathbb{E}[\zeta|\sigma(\eta)]\), and define \(\mathbb{P}[A|\eta] = \mathbb{P}^\eta A\) as \(\mathbb{E}[1_A|\sigma(\eta)]\).
Theorem 5.1, Part I. The $E^F \zeta$ as in the definition always exists and is a.s. unique. Moreover, the map $\zeta \mapsto E^F \zeta$ is a bounded linear map from $L^1(A)$ to $L^1(\mathcal{F})$ with $\|E^F \zeta\|_1 \leq \|\zeta\|_1$, and if $\zeta \geq 0$ then a.s. $E^F \zeta \geq 0$.

Proof. We may define a signed measure $\nu$ on $(\Omega, A)$ by $d\nu = \zeta dP$. Then $\nu \ll P$ on $A$, and so we also have $\nu \ll P$ on $\mathcal{F}$. Applying Radon-Nikodym Theorem to $P$ and $\nu$ on $(\Omega, \mathcal{F})$, we get an $\mathcal{F}$-measurable random variable $\eta$, which is integrable w.r.t. $P$, such that $d\nu = \eta dP$ on $\mathcal{F}$. Let $A \in \mathcal{F}$. From $d\nu = \eta dP$ on $\mathcal{F}$, we get $E[1_A \eta] = \nu(A)$. From $d\nu = \zeta dP$ on $A$, we get $E[1_A \zeta] = \nu(A)$. Thus, $E[1_A \eta] = E[1_A \zeta]$. So we get the existence of $E^F \zeta$.

Now suppose another $\mathcal{F}$-measurable random variable $\eta'$ satisfies $E[1_A \eta'] = E[1_A \zeta]$ for any $A \in \mathcal{F}$. Then $\eta$ and $\eta'$ are both $\mathcal{F}$-measurable, and for any $A \in \mathcal{F}$, we have $E[1_A \eta'] = E[1_A \zeta] = E[1_A \eta]$. So $\eta' = \eta$ a.s., and we get the a.s. uniqueness of $E^F \zeta$. In particular, we see that $E^F \zeta$ is a uniquely defined element in $L^1(\mathcal{F})$.

If $\zeta \geq 0$, then the above $\nu$ is a positive measure, which implies that the Radon-Nikodym derivative $d\nu/dP = E^F \zeta$ on $\mathcal{F}$ is a.s. nonnegative.

To see that the map $\zeta \mapsto E^F \zeta$ is linear, let $\zeta, \eta \in L^1(A)$ and $a, b \in \mathbb{R}$. Let $\zeta' = E^F \zeta$ and $\eta' = E^F \eta$. Then for any $A \in \mathcal{F}$, we have

$$E[1_A(a\zeta + b\eta)] = aE[1_A \zeta] + bE[1_A \eta] = aE[1_A \zeta'] + bE[1_A \eta'] = E[1_A(a\zeta' + b\eta')]$$

So we get $E[a\zeta + b\eta, \mathcal{F}] = aE^F \zeta + bE^F \eta$.

To see that $\|E^F \zeta\|_1 \leq \|\zeta\|_1$, we write $\zeta = \zeta^+ - \zeta^-$ such that $\zeta^+ \geq 0$ and $\|\zeta\|_1 = \|\zeta^+\|_1 + \|\zeta^-\|_1$. Let $\zeta'_+ = E^F \zeta^+_+$ and so

$$\|E^F \zeta\|_1 \leq \|\zeta'_+\|_1 + \|\zeta'_-\|_1 = E[\zeta'_+] + E[\zeta'_-] = E[\zeta^+] + E[\zeta^-] = \|\zeta^+\|_1 + \|\zeta^-\|_1 = \|\zeta\|_1.$$
Remark. We have a.s. \( \mathbb{E}^F \zeta = \zeta \) iff \( \zeta \) is \( \mathcal{F}^p \)-measurable, where \( \mathcal{F}^p \) is the \( \mathbb{P} \)-completion of \( \mathcal{F} \). If \( \zeta \) is \( \mathcal{F}^p \)-measurable, then there is an \( \mathcal{F} \)-measurable random variable \( \zeta' \) such that a.s. \( \zeta' = \zeta \). So for any \( A \in \mathcal{F} \), \( \int_A \zeta' \, d\mathbb{P} = \int_A \zeta \, d\mathbb{P} \), which implies that a.s. \( \mathbb{E}^F \zeta = \zeta' = \zeta \). On the other hand, if a.s. \( \mathbb{E}^F \zeta = \zeta \), we take \( \zeta' = \mathbb{E}^F \zeta \). Then \( \zeta' \) is \( \mathcal{F} \)-measurable and a.s. \( \zeta' = \zeta \). So \( \zeta \) is \( \mathcal{F}^p \)-measurable.

Example. Suppose \( \mathcal{F}_B \) is generated by a measurable partition \( \{B_1, \ldots, B_n\} \) of \( \Omega \). Now we do not assume that \( \mathbb{P}[B_k] > 0 \) for every \( k \). Since \( \mathbb{E}^B \zeta \) is \( \mathcal{F}_B \)-measurable, it is constant, say \( c_k \), on each \( B_k \). From \( \mathbb{E}[1_{B_k} \mathbb{E}^B \zeta] = \mathbb{E}[1_{B_k} \zeta] \) we get \( c_k \mathbb{P}[B_k] = \mathbb{E}[1_{B_k} \zeta] \). So if \( \mathbb{P}[B_k] > 0 \), then \( c_k = \mathbb{E}[\zeta|B_k] \); if \( \mathbb{P}[B_k] = 0 \), then \( c_k \) can be any number. The choice of \( c_k \) does not affect the a.s. uniqueness of \( \mathbb{E}[\zeta|\mathcal{F}_B] \).

Theorem 5.1, Part II. We use the setup as before.

(i) If \( \zeta \in L^\infty \), then \( \mathbb{E}^F \zeta \in L^\infty \), and \( \|\mathbb{E}^F \zeta\|_\infty \leq \|\zeta\|_\infty \).

(ii) For \( p \in (1, \infty) \), if \( \zeta \in L^p \), then \( \mathbb{E}^F \zeta \in L^p \) and \( \|\mathbb{E}^F \zeta\|_p \leq \|\zeta\|_p \).

(iii) If \( \mathcal{G} \subset \mathcal{F} \) is another \( \sigma \)-algebra, then \( \mathbb{E}^\mathcal{G} \mathbb{E}^F \zeta = \mathbb{E}^\mathcal{G} \zeta \).

(iv) If \( 0 \leq \zeta_n \uparrow \zeta \in L^1 \), then \( \mathbb{E}[\zeta_n|\mathcal{F}] \uparrow \mathbb{E}[\zeta|\mathcal{F}] \).

Proof. (i) Let \( M = \|\zeta\|_\infty \), then a.s. \( M \pm \zeta \geq 0 \), which implies that a.s.

\[
0 \leq \mathbb{E}^F [M \pm \zeta] = M \pm \mathbb{E}^F \zeta.
\]

So a.s. \( -M \leq \mathbb{E}^F \zeta \leq M \), i.e., \( \|\mathbb{E}^F \zeta\|_\infty \leq M = \|\zeta\|_\infty \).

(ii) Since the map \( \mathbb{E}^F \) is a contraction from \( L^1(A) \) to \( L^1(\mathcal{F}) \), and a contraction from \( L^\infty(A) \) to \( L^\infty(\mathcal{F}) \), by Marcinkiewicz interpolation theorem, it is also a contraction from \( L^p(A) \) to \( L^p(\mathcal{F}) \) for any \( p \in [1, \infty] \). This result also follows from Jensen’s inequality below.

(iii) Let \( \zeta' = \mathbb{E}^F \zeta \) and \( \zeta'' = \mathbb{E}^\mathcal{G} \zeta' \). Then \( \zeta'' \) is \( \mathcal{G} \)-measurable, and for any \( A \in \mathcal{G} \),

\[
\mathbb{E}[1_A \zeta''] = \mathbb{E}[1_A \zeta'] = \mathbb{E}[1_A \zeta].
\]

So we get \( \zeta'' = \mathbb{E}^\mathcal{G} \zeta \).

(iv) From \( 0 \leq \zeta_1 \leq \zeta_2 \leq \cdots \leq \zeta \) we get a.s.

\[
0 \leq \mathbb{E}[\zeta_1|\mathcal{F}] \leq \mathbb{E}[\zeta_2|\mathcal{F}] \leq \cdots \leq \mathbb{E}[\zeta|\mathcal{F}].
\]

Let \( \zeta' = \lim_{n \to \infty} \mathbb{E}[\zeta_n|\mathcal{F}] \). Then \( \zeta' \) is \( \mathcal{F} \)-measurable and a.s. \( \zeta' \leq \mathbb{E}[\zeta|\mathcal{F}] \). By Monotone convergence theorem and the averaging property,

\[
\mathbb{E}[\zeta'] = \lim_{n \to \infty} \mathbb{E}[\mathbb{E}[\zeta_n|\mathcal{F}]] = \lim_{n \to \infty} \mathbb{E}[\zeta_n] = \mathbb{E}[\zeta] = \mathbb{E}[\mathbb{E}[\zeta|\mathcal{F}]].
\]

This equality together with a.s. \( \zeta' \leq \mathbb{E}[\zeta|\mathcal{F}] \) implies that a.s. \( \mathbb{E}[\zeta|\mathcal{F}] = \zeta' = \lim_{n \to \infty} \mathbb{E}[\zeta_n|\mathcal{F}] \).
We refer to (i) and (ii) as the $L^\infty$-contractivity and $L^p$-contractivity, to (iii) as the chain rule, and to (iv) as the monotone convergence property.

**Theorem 5.2, Part III.**  (i) Let $\zeta \in L^1(\mathcal{A})$ and let $\eta$ be an $\mathcal{F}$-measurable random variable such that $\eta \zeta \in L^1(\mathcal{A})$. Then $\eta \mathbb{E}[\zeta|\mathcal{F}] \in L^1(\mathcal{F})$ and

$$
\mathbb{E}[\eta \zeta|\mathcal{F}] = \eta \mathbb{E}^F \zeta.
$$

(ii) Let $p, q \in [1, \infty]$ be such that $\frac{1}{p} + \frac{1}{q} = 1$. Let $\eta \in L^p(\mathcal{A})$ and $\zeta \in L^q(\mathcal{A})$. Then $\zeta \mathbb{E}^F \eta$, $\eta \mathbb{E}^F \zeta$, and $\mathbb{E}^F \zeta \mathbb{E}^F \eta$ are all integrable, and have the same expectation, i.e.,

$$
\mathbb{E}[\zeta \mathbb{E}^F \eta] = \mathbb{E}[\eta \mathbb{E}^F \zeta] = \mathbb{E}[\mathbb{E}^F \zeta \mathbb{E}^F \eta].
$$

**Proof.** (i) We first assume that $\eta$ is an $\mathcal{F}$-measurable simple random variable. Then there are $A_1, \ldots, A_n \in \mathcal{F}$ and $c_1, \ldots, c_n \in \mathbb{R}$ such that $\eta = \sum_{k=1}^n c_k 1_{A_k}$. Then $\eta \mathbb{E}^F \zeta \in L^1(\mathcal{F})$ because $\eta$ is bounded and $\mathbb{E}^F \zeta \in L^1(\mathcal{F})$. Moreover, for any $A \in \mathcal{F}$,

$$
\mathbb{E}[1_A \eta \mathbb{E}^F \zeta] = \mathbb{E}\left(\sum_{k=1}^n c_k 1_{A \cap A_k} \mathbb{E}^F \zeta\right) = \sum_{k=1}^n c_k \mathbb{E}[1_{A \cap A_k} \zeta] = \mathbb{E}[1_A \eta \zeta].
$$

So we get (5.4). Next, we assume that $\zeta, \eta \geq 0$, but do not assume that $\eta$ is simple. Then we can find a sequence of nonnegative $\mathcal{F}$-measurable simple random variables $(\eta_n)$ with $\eta_n \uparrow \eta$. For each $n$, we have $\eta_n \mathbb{E}^F \zeta \in L^1(\mathcal{F})$ and $\mathbb{E}[\eta_n \zeta|\mathcal{F}] = \eta_n \mathbb{E}^F \zeta$. Since $\eta_n \zeta \uparrow \eta \zeta$, and $\eta \zeta \in L^1(\mathcal{A})$, we get

$$
\mathbb{E}[\eta \zeta|\mathcal{F}] = \lim_n \mathbb{E}[\eta_n \zeta|\mathcal{F}] = \lim_n \eta_n \mathbb{E}[\zeta|\mathcal{F}] = \eta \mathbb{E}[\zeta|\mathcal{F}].
$$

So we again get (5.4). Finally, we do not assume that $\zeta, \eta \geq 0$. We may write $\zeta = \zeta_+ - \zeta_-$ and $\eta = \eta_+ - \eta_-$. Then for any $\sigma_1, \sigma_2 \in \{+, -\}$, from $|\eta_{\sigma_1}| \leq |\eta|$ and $|\zeta_{\sigma_2}| \leq |\zeta|$ we get $\eta_{\sigma_1} \zeta_{\sigma_2} \in L^1(\mathcal{A})$. The previous result implies that (5.4) holds for $\eta_{\sigma_1}$ and $\zeta_{\sigma_2}$. Using the linearity, we get (5.4) for $\eta$ and $\zeta$.

(ii) Since $\eta \in L^p(\mathcal{A})$ and $\zeta \in L^q(\mathcal{A})$, we get $\mathbb{E}^F \eta \in L^p(\mathcal{F})$ by $L^p$-contractivity of $\mathbb{E}^F$ and then $\zeta \mathbb{E}^F \eta \in L^1(\mathcal{A})$ by Hölder’s inequality. Applying (i) with $\mathbb{E}[\eta|\mathcal{F}]$ in place of $\eta$, we get

$$
\mathbb{E}[\zeta \mathbb{E}^F \eta|\mathcal{F}] = \mathbb{E}^F \zeta \mathbb{E}^F \eta.
$$

Symmetrically, we get $\mathbb{E}[\eta \mathbb{E}^F \zeta|\mathcal{F}] = \mathbb{E}[\eta \mathbb{E}^F \zeta]$. Taking expectation, we get (5.5). \qed

We refer to (i) as the pull-out property, and to (ii) as the self-adjointness. From (ii) we see that, for $1 \leq p < \infty$, the adjoint operator of the conditional expectation $\mathbb{E}^F : L^p(\mathcal{A}) \to L^p(\mathcal{F})$ is the conditional expectation $\mathbb{E}^F : L^q(\mathcal{A}) \to L^q(\mathcal{F})$. When $p = 2$, $\mathbb{E}^F : L^2(\mathcal{A}) \to L^2(\mathcal{F})$ is in fact the orthogonal projection onto $L^2(\mathcal{F})$.

**Lemma 5.2** (local property). Let $\mathcal{F}$ and $\mathcal{G}$ be two sub-$\sigma$-algebras of $\mathcal{A}$. Let $\zeta, \eta$ be two integrable random variables. Suppose there is $A \in \mathcal{F} \cap \mathcal{G}$ such that $A \cap \mathcal{F} = A \cap \mathcal{G}$ and a.s. $\zeta = \eta$ on $A$. Then a.s. $\mathbb{E}^F \zeta = \mathbb{E}^G \eta$ on $A$.  

62
Since $A \in \mathcal{F} \cap \mathcal{G}$ and $A \cap \mathcal{F} = A \cap \mathcal{G}$, both $1_A \mathbb{E}^F \zeta$ and $1_A \mathbb{E}^G \eta$ are $\mathcal{F} \cap \mathcal{G}$-measurable. For any $B \in \mathcal{F} \cap \mathcal{G}$, by the averaging property and that a.s. $\zeta = \eta$ on $A$,

$$\mathbb{E}[1_B 1_A \mathbb{E}^F \zeta] = \mathbb{E}[1_A \mathbb{E}^B \mathbb{E}^F \zeta] = \mathbb{E}[1_A \mathbb{E}^B \mathbb{E}^G \eta] = \mathbb{E}[1_A \mathbb{E}^{B \cap \mathcal{F}} \mathbb{E}^G \eta].$$

Since this holds for any $B \in \mathcal{F} \cap \mathcal{G}$, we get a.s. $1_A \mathbb{E}^F \zeta = 1_A \mathbb{E}^G \eta$. So we get the conclusion. □

**Lemma 5.5** (uniformly integrability, Doob). For any $\zeta \in L^1$, the family $\mathbb{E}^F \zeta$, where $\mathcal{F}$ is any sub-$\sigma$-algebra of $\mathcal{A}$, are uniformly integrable.

**Proof.** By the $L^1$-contractivity, $\{\mathbb{E}^F \zeta\}$ is $L^1$-bounded. In order to show that it is uniformly integrable, by Lemma 3.10, it suffices to show that $\mathbb{E}[1_A \mathbb{E}^F \zeta] \to 0$ as $A \in \mathcal{A}$ and $\mathbb{P} A \to 0$, uniformly in $\mathcal{F}$. So we need to show that if $\mathcal{F}_1, \mathcal{F}_2, \ldots$ are sub-$\sigma$-algebras of $\mathcal{A}$, and $A_1, A_2, \ldots \in \mathcal{A}$ satisfy $\mathbb{P} A_n \to 0$, then $\mathbb{E}[1_{A_n} \mathbb{E}^{\mathcal{F}_n} \zeta] \to 0$. By the self-adjointness, Since $\zeta \in L^1$ and $1_{A_n} \in L^\infty$,

$$\mathbb{E}[1_{A_n} \mathbb{E}^{\mathcal{F}_n} \zeta] = \mathbb{E}[\zeta \mathbb{E}^{\mathcal{F}_n} [1_{A_n}]].$$

Since $\mathbb{E}[\mathbb{E}^{\mathcal{F}_n} [1_{A_n}]] = \mathbb{P} A_n \to 0$, we know that $\mathbb{E}^{\mathcal{F}_n} [1_{A_n}] \to 0$ in $L^1$. So $\mathbb{E}^{\mathcal{F}_n} [1_{A_n}] \xrightarrow{P} 0$. Thus, $\zeta \mathbb{E}^{\mathcal{F}_n} [1_{A_n}] \xrightarrow{P} 0$. By dominated convergence theorem (for convergence in probability), we get $\mathbb{E}[\zeta \mathbb{E}^{\mathcal{F}_n} [1_{A_n}]] \to 0$, as desired. □

We are going to use conditional expectation to define conditional distribution (or law). Suppose $\mathcal{F}$ is a sub-$\sigma$-algebra of $\mathcal{A}$, and $\zeta$ is a random element in a measurable space $(S, \mathcal{S})$. For every $A \in \mathcal{S}$, $\mathbb{P}^F \{\zeta \in A\}$ is an element in $L^1(\mathcal{F})$, which satisfies a.s. $0 \leq \mathbb{P}^F \{\zeta \in A\} \leq 1$, $\mathbb{P}^F \{\zeta \in S\} = 1$, and $\mathbb{P}^F \{\zeta \in \emptyset\} = 0$. Suppose for each $A \in \mathcal{S}$, we choose a representative, say $\zeta_A$, of $\mathbb{P}^F \{\zeta \in A\}$. Such $\zeta_A$ is an $\mathcal{F}$-measurable random variable. We may choose $\zeta_A$ such that $0 \leq \zeta_A \leq 1$, $\zeta_A \equiv 1$, and $\zeta_A \equiv 0$. Consider the map $\nu : \Omega \times \mathcal{S} \to [0, 1]$ defined by

$$\nu(\omega, A) = \zeta_A(\omega).$$

We find that, for any $A \in \mathcal{S}$, $\nu(\cdot, A)$ is an $\mathcal{F}$-measurable random variable. On the other hand, by the linearity and monotone convergence property of conditional expectation, we have

a.s. $\nu(\cdot, A) = \sum_{n=1}^{\infty} \nu(\cdot, A_n)$, if $A$ is a disjoint union of $A_1, A_2, \ldots \in \mathcal{S}$.

This means that there is an exceptional event $N$ depending on $A_1, A_2, \ldots$ with $\mathbb{P} N = 0$ such that

$$\mu(\omega, A) = \sum_{n=1}^{\infty} \nu(\omega, A_n), \quad \forall \omega \in \Omega \setminus N.$$  \hfill (5.6)

Since there are uncountably many such sequences, in general, we may not be able to find a common exceptional null set, which is an $\mathcal{F}$-measurable set $N$ with $\mathbb{P} N = 0$, such that (5.6) holds for any $A, A_1, A_2, \ldots \in \mathcal{A}$ such that $A$ is a disjoint union of $A_1, A_2, \ldots$. However if such $N$ does exist, we may modify the value of each $\zeta_A$ as follows. Pick $s_0 \in S$. For every $A \in \mathcal{S}$, we
do not change the value of $\zeta_A$ on $\Omega \setminus N$, but for $\omega \in N$, we now define $\zeta_A(\omega) = 1_A(s_0) = \delta_{s_0} A$. Then the new $\zeta_A$ are still representatives of $\mathbb{P}^F[\zeta \in A]$, and (5.6) holds true for all $\omega \in \Omega$. So we find that $\nu$ is a probability kernel from $(\Omega, \mathcal{F})$ to $(S, \mathcal{S})$.

**Definition.** Suppose $\nu$ is a probability kernel from $(\Omega, \mathcal{F})$ to $(S, \mathcal{S})$ and satisfies that for any $A \in \mathcal{S}$, a.s.

$$\mathbb{P}^F[\zeta \in A] = \nu(\cdot, A).$$

Then $\nu$ is called a (regular) conditional distribution (or law) of $\zeta$, given $\mathcal{F}$. When such $\nu$ exists, we write it as $\text{Law}(\zeta|\mathcal{F})$ or $\text{Law}^F(\zeta)$.

A conditional law is convenient for us. Suppose further that $\eta$ is a random element in another measurable space $(T, \mathcal{T})$. We may then consider conditional law of $\zeta$ given $\sigma(\eta)$. If such a conditional law $\nu$ exits, then it is a probability kernel from $(\Omega, \sigma(\eta))$ to $(S, \mathcal{S})$. Recall that, for any probability kernel $\mu$ from $(T, \mathcal{T})$ to $(S, \mathcal{S})$, $(\omega, A) \mapsto \mu(\eta(\omega), A)$ is a probability kernel from $(\Omega, \sigma(\eta))$ to $(S, \mathcal{S})$. It is desirable to have a probability kernel $\mu$ such that $\nu(\omega, A) = \mu(\eta(\omega), A)$.

Then for any $A \in \mathcal{S}$, we have

$$\mathbb{P}^\eta[\zeta \in A] = \mu(\eta, A), \quad \text{a.s.} \quad (5.7)$$

When such $\mu$ exists, we then have the existence of $\text{Law}(\zeta|\eta)$, which equals $\mu(\eta, \cdot)$. The following theorem concerns the existence of such kernel.

**Theorem 5.3.** Let $(S, \mathcal{S})$ and $(T, \mathcal{T})$ be two measurable spaces, where $S$ is a Borel space. Let $\zeta$ and $\eta$ be two random elements in $S$ and $T$, respectively. Then there is a probability kernel $\mu$ from $(T, \mathcal{T})$ to $(S, \mathcal{S})$ such that for any $A \in \mathcal{S}$, (5.7) holds. Moreover, such $\mu$ is $\text{Law}(\eta)$-a.s. unique, which means that if another $\mu'$ satisfies the same property, then there exists $N \in \mathcal{T}$ with $\mathbb{P} \circ \eta^{-1}N = 0$ such that $\mu' \equiv \mu$ on $(T \setminus N) \times \mathcal{S}$.

**Corollary.** If $\zeta$ is a random element in a Borel space $(S, \mathcal{S})$, then for any sub-$\sigma$-algebra $\mathcal{F}$ of $\mathcal{A}$, the conditional law $\text{Law}(\zeta|\mathcal{F})$ exists and is a.s. unique.

**Proof of the corollary.** Take $(T, \mathcal{T}) = (\Omega, \mathcal{F})$. Let $\eta : \Omega \rightarrow \Omega$ be the identity. Since $\mathcal{F} \subset \mathcal{A}$, $\eta$ is $\mathcal{A}/\mathcal{F}$-measurable. We have $\text{Law}(\eta) = \mathbb{P}$ and $\sigma(\eta) = \mathcal{F}$. By Theorem 5.3, there is a probability kernel $\mu$ from $(\Omega, \mathcal{F})$ to $(S, \mathcal{S})$ such that for any $A \in \mathcal{S}$, a.s. $\mathbb{P}^F[\zeta \in A] = \mathbb{P}^\eta[\zeta \in A] = \mu(\eta, A) = \mu(\cdot, A)$. So $\mu = \text{Law}(\zeta|\mathcal{F})$. By Theorem 5.3, such $\mu$ is $\text{Law}(\eta)$-a.s. unique. Since $\text{Law}(\eta) = \mathbb{P}$, such $\mu$ is a.s. unique.

**Proof of Theorem 5.3.** We may assume that $S \in \mathcal{B}({\mathbb{R}})$. Then $\zeta$ is a random variable. For every $r \in \mathbb{Q}$, we consider a representative of $\mathbb{P}[\zeta \leq r|\eta]$, which is an $\eta$-measurable random variable taking values in $[0, 1]$. By Lemma 1.13, for each $r \in \mathbb{Q}$, there is a random variable $f_r$ defined on $T$ such that

$$\text{a.s.} \quad \mathbb{P}^\eta[\zeta \leq r] = f_r(\eta). \quad (5.8)$$

For any $r_1, r_2 \in \mathbb{Q}$ with $r_1 < r_2$, by positivity we have a.s. $f_{r_1}(\eta) \leq f_{r_2}(\eta)$, which implies that $\mathbb{P} \circ \eta^{-1}$-a.s. $f_{r_1} \leq f_{r_2}$. By monotone convergence property, we have a.s. $\lim_{n \to +\infty} f_n(\eta) = 1$ and $\lim_{n \to +\infty} f_{-n}(\eta) = 0$. Thus, $\mathbb{P} \circ \eta^{-1}$-a.s. $\lim_{\mathbb{Z} \ni n \to +\infty} f_n = 1$ and $\lim_{\mathbb{Z} \ni n \to -\infty} f_n = 0$. Since
there are at most countably many pairs \((r_1, r_2)\) with \(r_1, r_2 \in \mathbb{Q}\), we may find \(N \in \mathcal{T}\) with \(\mathbb{P}^{-1}N = 0\) such that for \(t \in T \setminus N\), \(Q \ni r \mapsto f_r(t)\) is increasing, and \(\lim_{n \to +\infty} f_n(t) = 1\) and \(\lim_{n \to -\infty} f_n(t) = 0\). Then we get \(\lim_{\mathbb{Q} \ni r \to +\infty} f_r(t) = 1\) and \(\lim_{\mathbb{Q} \ni r \to -\infty} f_r(t) = 0\) for \(t \in T \setminus N\). We define a measurable function \(F : T \times \mathbb{R} \to [0, 1]\) such that

\[
F(t, x) = \begin{cases} 
\inf_{\mathbb{Q} \ni r > x} f_r(t), & t \in T \setminus N; \\
1_{[0, \infty)}(x), & t \in N.
\end{cases}
\]

Then for every \(t \in T\), \(F(t, \cdot)\) is increasing and right continuous and satisfies \(\lim_{x \to +\infty} F(t, x) = 1\) and \(\lim_{x \to -\infty} F(t, x) = 0\), and so is a distribution of some probability measure \(m(t, \cdot)\) on \(\mathbb{R}\) (when \(t \in N\), \(m(t, \cdot) = \delta_0\) by the construction). From the measurability of \(F\), we see that for any \(x \in \mathbb{R}\), \(t \mapsto m(t, (\infty, x])\) is \(\mathcal{T}\)-measurable. Using a monotone class argument, we conclude that \(m\) is a probability kernel from \(T\) to \(\mathbb{R}\).

By (5.8) and the monotone convergence property of conditional expectation, for any \(x \in \mathbb{R}\), a.s.

\[
m(\eta, (\infty, x]) = F(\eta, x) = \inf_{\mathbb{Q} \ni r > x} \mathbb{P}^\eta[\zeta \leq r] = \mathbb{P}^\eta[\zeta \in (\infty, x]].
\]

Using a monotone class argument based on the a.s. monotone convergence property, we may extend the last relation to

\[
m(\eta, B) = \mathbb{P}^\eta[\zeta \in B] \text{ a.s. } \forall B \in \mathcal{B}(\mathbb{R}).
\] (5.9)

In particular, we have a.s. \(m(\eta, S^c) = 0\), i.e., \(\mathbb{P} \circ \eta^{-1}\text{-a.s. } m(\cdot, S^c) = 0\). Taking \(s_0 \in S\), (5.9) remains true if \(m\) is replaced by the kernel \(\mu\) from \(T\) to \(S\) defined by

\[
\mu(t, \cdot) = \begin{cases} 
m(t, \cdot), & \text{if } m(t, S^c) = 0; \\
\delta_{s_0}, & \text{if } m(t, S^c) > 0.
\end{cases}
\]

Such \(\mu\) is what we need. If there is another probability kernel \(\mu'\) from \(T\) to \(S\) with the stated property, then for any \(r \in \mathbb{Q}\), a.s.

\[
\mu(\eta, (\infty, r]) = \mathbb{P}^\eta[\zeta \leq r] = \mu'(\eta, (\infty, r]).
\]

Since \(\mathbb{Q}\) is countable, we can exchange “for any \(r \in \mathbb{Q}\)” with “a.s.”. A monotone class argument yields a.s. \(\mu(\eta, \cdot) = \mu'(\eta, \cdot)\), and so \(\mathbb{P} \circ \eta^{-1}\text{-a.s. } \mu = \mu'\).

There are two trivial cases. If \(\mathcal{F} = \{\Omega, \emptyset\}\), then a probability kernel from \((\Omega, \mathcal{F})\) to \((S, \mathcal{S})\) is just a probability measure on \((S, \mathcal{S})\). In this case, the conditional law \(\text{Law}(\zeta|\mathcal{F})\) agrees with \(\text{Law}(\zeta)\), which is often referred as the unconditional law of \(\zeta\). Another trivial case is \(\mathcal{F} = \mathcal{A}\).

**Exercise.** Find the conditional law \(\text{Law}(\zeta|\mathcal{A})\).

Recall that if \(f : S \to \mathbb{R}\) is measurable such that \(\mathbb{E}|f(\zeta)| < \infty\), then

\[
\mathbb{E}f(\zeta) = \int_S f(s) \text{Law}(\zeta)(ds).
\]

The following theorem extends this equality to conditional laws.
Proof. We first prove (5.11). We write \( \eta \) when using \( \mu \) expressed by \( \varphi \). Pull out property of conditional expectation, \( \int_s \mapsto \mapsto \) function \( f \) is \( \tilde{T} \), and \( \eta \) is an indicator function, then \( \nu \) is \( \tilde{T} \), and \( \eta \) is \( \nu \)-measurable, and equals \( \mathbb{E}[f(\zeta, \eta) | F](\omega) \). In short, this means a.s.

\[
\mathbb{E}[f(\zeta, \eta) | F] = \int f(s, \eta) \mathbb{L}(\zeta | F)(ds). 
\] (5.10)

Integrating (5.10), we get the commonly used formula

\[
\mathbb{E}[f(\zeta, \eta)] = \mathbb{E} \int f(s, \eta) \mathbb{L}(\zeta | F)(ds). 
\] (5.11)

When \( \eta \) disappears, (5.10) becomes \( \mathbb{E}[f(\zeta) | F] = \int f(s) \mathbb{L}(\zeta | F)(ds) \).

Proof. We first prove (5.11). We write \( \nu \) for \( \mathbb{L}(\zeta | F) \). First, suppose \( f = 1_{B \times C} \), where \( B \in \mathcal{S} \) and \( C \in \mathcal{T} \). Then \( \int f(s, \eta)\nu(ds) = 1_{\eta \in C}\nu B \) is \( F \)-measurable because \( \eta \in F \). By \( \eta \in F \) and the pull-out property of conditional expectation,

\[
\mathbb{E}[f(\zeta, \eta)] = \mathbb{E}[\mathbb{E}[1_{\zeta \in B}1_{\eta \in C} | F]] = \mathbb{E}[1_{\eta \in C}\mathbb{P}[\zeta \in B]] = \mathbb{E}[1_{\eta \in C}\nu B] = \mathbb{E} \int f(s, \eta)\nu(ds).
\]

So we proved (5.11) for \( f = 1_{B \times C} \). By a monotone class argument, we then conclude that, if \( f \) is an indicator function, then \( \int f(s, \eta)\nu(ds) \) is \( F \)-measurable and (5.11) holds. Using linearity and monotone convergence, we see that the measurability and (5.11) holds for any measurable function \( f \geq 0 \). In particular, if \( \mathbb{E}[f(\zeta, \eta)] < \infty \), we find that a.s. \( \int f(s, \eta)\nu(ds) < \infty \). So \( s \mapsto f(s, \eta) \) is a.s. integrable w.r.t \( \nu \), and the measurability holds outside a null set on which \( \int f(s, \eta)\nu(ds) = \infty \).

We now return to (5.10). Fix a measurable \( f : S \times T \to \mathbb{R}_+ \) with \( \mathbb{E}[f(\zeta, \eta)] < \infty \), and let \( A \in F \). Then \( \eta_A := (\eta, 1_A) \) is an \( F \)-measurable random element in \( T \times \{0, 1\} \). Note that \( 1_A f(\zeta, \eta) \) can be expressed as \( f(\zeta, \eta_A) \) such that \( \tilde{f}(s, (t, 1)) = f(s, t) \) and \( \tilde{f}(s, (t, 0)) = 0 \). Such \( f \) is \( S \times (T \times \{0, 1\}) \)-measurable. Applying (5.11) with \( T \times \{0, 1\} \) in place of \( T \), \( \eta_A \) in place of \( \eta \), and \( \tilde{f} \) in place of \( f \), we get

\[
\mathbb{E}[1_A f(\zeta, \eta)] = \mathbb{E}[\tilde{f}(\zeta, \eta_A)] = \mathbb{E} \int \tilde{f}(s, \eta_A)\nu(ds) = \mathbb{E}[1_A \int f(s, \eta)\nu(ds)].
\]

Since \( \int f(s, \eta)\nu(ds) \) is \( F \)-measurable, we get (5.10) for \( f \geq 0 \). The general result follows by taking differences.

Remark. For two random elements \( \zeta \) and \( \eta \) in \( T \) and \( S \), respectively, if \( \mathbb{L}(\zeta | \eta) \) exists and is expressed by \( \mu(\eta, \cdot) \) for a probability kernel \( \mu \) from \( T \) to \( S \), then we may recover the \( \mathbb{L}(\zeta, \eta) \) using \( \mu \) and \( \nu := \mathbb{L}(\eta) \). For any \( A \in S \times T \), applying (5.11) to \( F = \sigma(\eta) \) and \( f = 1_A \), we get

\[
\mathbb{P}[(\zeta, \eta) \in A] = \mathbb{E} \int_S 1_A(s, \eta)\mu(\eta, ds) = \int_T \nu(dt) \int_S 1_A(s, t)\mu(t, ds).
\]
Thus, $\nu \otimes \mu$ as a probability measure on $T \times S$ is the law of $(\eta, \zeta)$. When $\zeta \perp \eta$, $\mu$ is the constant Law$(\zeta)$, and $\nu \otimes \mu$ is just the product measure Law$(\eta) \times$ Law$(\zeta)$.

**Example.** Suppose $\zeta$ and $\eta$ are two random variables such that the law of $(\zeta, \eta)$ is absolutely continuous w.r.t. the Lebesgue measure on $\mathbb{R}^2$, and the Radon-Nikodym derivative is $f$. Define $f_\eta$ on $\mathbb{R}$ by $f_\eta(y) = \int_{\mathbb{R}} f(x,y) dx \in [0, \infty]$. Then $f_\eta$ is the density of the law of $\eta$ against the Lebesgue measure on $\mathbb{R}$ because for any $B \in \mathcal{B}$,

$$\mathbb{P}[\eta \in B] = \mathbb{P}[(\zeta, \eta) \in \mathbb{R} \times B] = \int_B dy \int_{\mathbb{R}} dx f(x,y) = \int_B f_\eta(y) dy.$$ 

So Law$(\eta)$-a.s. $f_\eta \in (0, \infty)$. Now we define a probability kernel $\mu$ from $\mathbb{R}$ to $\mathbb{R}$ such that for $y \in \mathbb{R}$ and $A \in \mathcal{B}$, if $f_\eta(y) \in (0, \infty)$, then

$$\mu(y,A) = \frac{1}{f_\eta(y)} \int_A f(x,y) dx;$$

and otherwise, $\mu(y,A) = \delta_0(A)$. This means that for Law$(\eta)$-a.s. all $y$, $\mu(y, \cdot)$ has a density, which is $\frac{f(x,y)}{f_\eta(y)}$ w.r.t. the Lebesgue measure. The choice of $\mu(y, \cdot)$ when $f_\eta(y) \in \{0, \infty\}$ is not important. We claim that Law$(\zeta|\eta) = \mu(\eta, \cdot)$. To see this, note that for any $A, B \in \mathcal{B}$, letting $B' = B \cap f_\eta^{-1}((0, \infty))$, we get

$$\mathbb{E}[1_{\eta \in B} 1_{\zeta \in A}] = \mathbb{E}[1_{\eta \in B'} 1_{\zeta \in A}] = \int_{B'} \int_A f(x,y) dx dy = \int_{B'} f_\eta(y) \int_A \frac{f(x,y)}{f_\eta(y)} dx dy$$

$$= \int_{B'} f_\eta(y) \mu(y,A) dy = \mathbb{E}[1_{B'} \mu(\eta, A)] = \mathbb{E}[1_B \mu(\eta, A)].$$

For a fixed $A \in \mathcal{B}$, since the above formula holds for any $B \in \mathcal{B}$, we get a.s. $\mathbb{P}[\zeta \in A|\eta] = \mu(\eta, A)$. Since this holds for any $A \in \mathcal{B}$, we get Law$(\zeta|\eta) = \mu(\eta, \cdot)$.

**Corollary** (Jensen’s inequality for conditional expectation). Let $\zeta$ be an integrable random variable. Let $\mathcal{F} \subset \mathcal{A}$ be a $\sigma$-algebra. Let $f : \mathbb{R} \to \mathbb{R}$ be convex such that $f(\zeta)$ is integrable. Then

$$\mathbb{E}[f(\zeta)|\mathcal{F}] \geq f(\mathbb{E}[\zeta|\mathcal{F}]).$$

**Proof.** Applying (5.10) and using the unconditional Jensen’s inequality, we get

$$\mathbb{E}[f(\zeta)|\mathcal{F}] = \int f(s) \text{Law}(\zeta|\mathcal{F})(ds) \geq f\left(\int s \text{Law}(\zeta|\mathcal{F})(ds)\right) = f(\mathbb{E}[\zeta|\mathcal{F}]).$$

Applying this Jensen’s inequality to $f(x) = |x|^p$, $p \in (1, \infty)$, we see that for $\zeta \in L^p$, $\mathbb{E}[|\zeta|^p] \geq \mathbb{E}[|\mathbb{E}[\zeta|\mathcal{F}]|^p]$, and so we again get the $L^p$-contractivity $\|\mathbb{E}[\zeta|\mathcal{F}]\|_p \leq \|\zeta\|_p$. 

\[ \square \]
We now define conditional independence. For sub-$\sigma$-algebras $G$, $F_1, \ldots, F_n$ of $A$, we say that $F_1, \ldots, F_n$ are conditionally independent, given $G$, if

$$P^G \left[ \bigcap_{k=1}^n B_k \right] = \prod_{k=1}^n P^G[B_k] \text{ a.s., } B_k \in F_k, \quad 1 \leq k \leq n.$$ 

If $(F_t)_{t \in T}$ is an infinite family of sub-$\sigma$-algebras of $A$, we say that they are conditionally independent, given $G$, if the same property holds for every finite subcollection $F_{t_1}, \ldots, F_{t_n}$. Conditional independence involving events $A_t$, or random elements $\zeta_t$, $t \in T$, is defined as before in terms of the induced $\sigma$-algebras $\sigma(A_t)$ and $\sigma(\zeta_t)$. We use $\perp_G$ to denote pairwise conditional independence, given $G$.

If $\zeta$ is $G$-measurable, then for any $P^G[\zeta \in A] = 1_{\zeta \in A}$, and so $\zeta$ is conditionally independent of any $F \subset A$, given $G$. If $F_t$, $t \in T$, are all independent of $G$, then for any $B \in \bigvee_{t \in T} F_t$, $P^G[B] = P[B]$, and so $F_t$, $t \in T$, are conditionally independent, given $G$, iff $F_t$, $t \in T$, are unconditionally independent.

**Proposition 5.6** (conditional independence, Doob). Let $F, G, H$ be sub-$\sigma$-algebras of $A$. Then $F \perp_G H$ iff

$$P[H|F, G] = P[H|G] \text{ a.s., } \forall H \in H.$$ (5.12)

**Proof.** Assuming (5.12) and using the chain rule and pull-out properties, we get for any $F \in F$ and $H \in H$,

$$P^G[F \cap H] = E^G[E^{F \cap G}[1_F 1_H]] = E^G[1_F E^{F \cap G}[1_H]] = E^G[1_F 1_H P^G[F]] = P^G[H] P^G[F],$$

which shows that $F \perp_G H$. Conversely, if $F \perp_G H$, then for any $F \in F$, $G \in G$, and $H \in H$,

By a monotone class argument, we get that for any $A \in F \vee G$,

$$E[1_A P^G[H]] = P[A \cap H].$$

Since $P^G[H]$ is $F \vee G$-measurable, we get (5.12).

From now on, for every sub-$\sigma$-algebra $F$ of $A$, we use $F$ to denote the completion of $F$ w.r.t. $P$.

**Corollary 5.7.** Let $F, G, H$ be sub-$\sigma$-algebras of $A$. Then

(i) $F \perp_G H$ iff $F \perp_G (G, H)$;

(ii) $F \perp_G F$ iff $F \subset G$.  

68
Proof. (i) By Proposition 5.6, both relations are equivalent to
\[ P[F|G,H] = P[F|G] \quad \text{a.s.,} \quad \forall F \in \mathcal{F}. \]

(ii) If \( \mathcal{F} \perp G \mathcal{F} \), then by Proposition 5.6, for any \( F \in \mathcal{F} \),
\[ \text{a.s. } 1_F = P[F|\mathcal{F},G] = P[F|G], \]
which implies that \( F \in \mathcal{G} \). So \( \mathcal{F} \subset \mathcal{G} \). On the other hand, if \( \mathcal{F} \subset \mathcal{G} \), then for any \( F \in \mathcal{F} \),
\[ \text{a.s. } P[F|G] = P[F|\mathcal{G}] = 1_F = P[F|\mathcal{F},G]. \]

Using Proposition 5.6 again, we get \( \mathcal{F} \perp G \mathcal{F} \). \( \square \)

**Proposition 5.8** (chain rule). Let \( \mathcal{G}, \mathcal{H}, \mathcal{F}_1, \mathcal{F}_2, \ldots \) be sub-\( \sigma \)-algebras of \( \mathcal{A} \). Then the following conditions are equivalent.

(i) \( \mathcal{H} \perp G (\mathcal{F}_1, \mathcal{F}_2, \ldots) \);

(ii) \( \mathcal{H} \perp G, \mathcal{F}_1, \ldots, \mathcal{F}_n, \mathcal{F}_{n+1} \) for all \( n \geq 0 \).

**Proof.** If (i) holds, then for any \( n \geq 0 \), \( \mathcal{H} \perp G (\mathcal{F}_1, \ldots, \mathcal{F}_n) \). By Proposition 5.6, for any \( H \in \mathcal{H} \) and \( n \geq 0 \), a.s.
\[ P[H|G,\mathcal{F}_1,\ldots,\mathcal{F}_n] = P[H|G] = P[H|G,\mathcal{F}_1,\ldots,\mathcal{F}_n,\mathcal{F}_{n+1}], \]
which implies (ii) by Proposition 5.6.

Suppose (ii) holds. By Proposition 5.6, for any \( H \in \mathbb{H} \) and \( n \geq 0 \), a.s.
\[ P[H|G,\mathcal{F}_1,\ldots,\mathcal{F}_n] = P[H|G,\mathcal{F}_1,\ldots,\mathcal{F}_n,\mathcal{F}_{n+1}]. \]

When \( n = 0 \), this means a.s. \( P[H|G] = P[H|G,\mathcal{F}_1] \). Thus, for any \( m \geq 1 \), a.s.
\[ P[H|G] = P[H|G,\mathcal{F}_1,\ldots,\mathcal{F}_m]. \]

So by Proposition 5.6,
\[ \mathcal{H} \perp G (\mathcal{F}_1, \ldots, \mathcal{F}_m), \quad m \geq 1. \]

By a monotone class argument, we get (i). \( \square \)

**Remark.** Taking \( G = \{ \Omega, \emptyset \} \), we find that \( \mathcal{H} \perp (\mathcal{F}_1, \mathcal{F}_2, \ldots) \) iff \( \mathcal{H} \perp \mathcal{F}_1, \ldots, \mathcal{F}_n, \mathcal{F}_{n+1} \) for all \( n \geq 0 \).

**Exercise.** Do Problems 1, 2, 4, 5, 7, 8 in Chapter 5. Note that Problems 4, 5 define \( \mathbb{E}^F \zeta \) for any \( \mathbb{R}_+ \)-valued random variable (may not be integrable); Problems 7, 8 extend Fatou’s lemma and dominated convergence theorem to conditional expectation.
6 Filtration and Stopping Times

Consider a measurable space \((\Omega, \mathcal{A})\). Let \(T \subset \mathbb{R}\) be an index set. A filtration on \(T\) is an increasing family of \(\sigma\)-algebras \(\mathcal{F}_t \subset \mathcal{A}, t \in T\). This means that \(s < t \in T\) implies that \(\mathcal{F}_s \subset \mathcal{F}_t\). We understand \(\mathcal{F}_t\) as the knowledge at the time \(t\) with the memory of the past being kept. The increasingness of \(\mathcal{F}_t\) reflects the arrow of time. From now on, we use \(\mathcal{F}\) to denote a filtration rather than a \(\sigma\)-algebra. Let \((S, \mathcal{S})\) be a measurable space. An \(S\)-valued stochastic process \(X\) with index \(T\) is a family of measurable mappings \(X_t, t \in T\), from \(\Omega\) to \(S\). It is called \(\mathcal{F}\)-adapted if \(X_t\) is \(\mathcal{F}_t\)-measurable for every \(t \in T\). If we start with \(X = (X_t)_{t \in T}\), and define \(\mathcal{F}_t = \sigma(X_s: s \leq t), t \in T\), then \(\mathcal{F} = (\mathcal{F}_t)\) is called the filtration induced by \(X\). It is the smallest filtration to which \(X\) is adapted.

Given a filtration \(\mathcal{F} = (\mathcal{F}_t)_{t \in T}\), a random variable \(\tau\) taking values in \(T \cup \{\sup T\}\) is called an \(\mathcal{F}\)-stopping time or \(\mathcal{F}\)-optional time if for any \(t \in T\), \(\{\tau \leq t\} = \{\omega \in \Omega : \tau(\omega) \leq t\} \in \mathcal{F}_t\). Intuitively, \(\tau\) is a stopping time means that we can determine whether \(\tau\) happens using only the knowledge of the past.

**Exercise**. Show that if \(T\) is countable, then \(\tau\) is an \(\mathcal{F}\)-stopping time iff \(\{\tau = t\} \in \mathcal{F}_t, \forall t \in T\).

**Exercise**. Show that the supremum of a sequence of \(\mathcal{F}\)-stopping times is an \(\mathcal{F}\)-stopping time, and the minimum of finitely many \(\mathcal{F}\)-stopping times is an \(\mathcal{F}\)-stopping time. We will see that the infimum of a sequence of \(\mathcal{F}\)-stopping times may not be an \(\mathcal{F}\)-stopping time.

**Example**. Suppose \((\Omega, \mathcal{F}, \mathbb{P})\) is a probability space, and \(\zeta_1, \zeta_2, \ldots\) is an i.i.d. sequence of random variables with Bernoulli distribution \(B(1/2)\). Let \(\mathcal{F} = (\mathcal{F}_n)_{n \in \mathbb{N}}\) be the filtration generated by \(\zeta = (\zeta_n)\). Let \(X_n = \sum_{k=1}^{n} \zeta_k, n \in \mathbb{N}\). Then \(X = (X_n)_{n \in \mathbb{N}}\) is an \(\mathcal{F}\)-adapted process. Let \(N \in \mathbb{N}\). Let \(\tau_N\) be the first \(n\) such that \(X_n = N\); if such time does not exist, we set \(\tau_N = \infty\). Then \(\tau_N\) is an \(\mathcal{F}\)-stopping time because for any \(n \in \mathbb{N}\),

\[
\{\tau_N \leq n\} = \bigcup_{k=1}^{n} \{X_k = N\} \in \mathcal{F}_n.
\]

On the other hand, let \(\sigma_N\) be the last \(n\) such that \(X_n = N\); and when such time does not exist, let \(\sigma_N = \infty\). Then \(\sigma_N\) is not a stopping time because

\[
\{\sigma_N = n\} = \{X_n = N\} \cap \{\zeta_{n+1} = 1\} \in \mathcal{F}_{n+1} \setminus \mathcal{F}_n.
\]

Intuitively, \(\sigma_N\) is not a stopping time because we need future information to determine whether it happens.

For an \(\mathcal{F}\)-stopping time \(\tau\), we define

\[
\mathcal{F}_\tau := \{A \in \mathcal{A} : A \cap \{\tau \leq t\} \in \mathcal{F}_t, \forall t \in T\}.
\]

It is easy to see that \(\mathcal{F}_\tau\) is a \(\sigma\)-algebra. We understand \(\mathcal{F}_\tau\) as the knowledge at the random time \(\tau\).
Exercise. Show that for any fixed $t_0 \in T$, the constant time $\tau = t_0$ is an $\mathcal{F}$-stopping time, and the $\sigma$-algebra $\mathcal{F}_\tau$ associated with such $\tau$ agrees with the $\mathcal{F}_{t_0}$. Thus, $\tau$ and $\mathcal{F}_\tau$ naturally extend $t$ and $\mathcal{F}_t$ for deterministic times $t \in T$.

Lemma 6.1. For any $\mathcal{F}$-stopping times $\sigma$ and $\tau$, we have

(i) $\tau$ is $\mathcal{F}_\tau$-measurable;

(ii) $\mathcal{F}_\sigma \cap \{ \sigma \leq \tau \} \subset \mathcal{F}_\sigma \wedge \tau = \mathcal{F}_\sigma \cap \mathcal{F}_\tau \subset \mathcal{F}_\tau$.

(iii) $\mathcal{F}_\sigma \cap \{ \sigma = \tau \} = \mathcal{F}_\tau \cap \{ \sigma = \tau \}$.

(iv) $\{ \sigma < \tau \}, \{ \sigma \leq \tau \}, \{ \sigma = \tau \} \in \mathcal{F}_\sigma \cap \mathcal{F}_\tau$.

(v) If $\sigma \leq \tau$, then $\mathcal{F}_\sigma \subset \mathcal{F}_\tau$.

Proof. Let $A \in \mathcal{F}_\sigma$. Then for any $t \in T$,

$$(A \cap \{ \sigma \leq t \}) \cap \{ \tau \leq t \} = (A \cap \{ \sigma \leq t \}) \cap \{ \tau \leq t \} \cap \{ \sigma \wedge t \leq \tau \wedge t \}. $$

Since $A \in \mathcal{F}_\sigma$, $A \cap \{ \sigma \leq t \} \in \mathcal{F}_t$. Since $\sigma$ is an $\mathcal{F}$-stopping time, $\{ \tau \leq t \} \in \mathcal{F}_t$. For deterministic times $t$, $\{ \sigma \wedge t \leq \tau \wedge t \} \subset \mathcal{F}_t$. Thus,

$$\mathcal{F}_\sigma \cap \{ \sigma \leq \tau \} \subset \mathcal{F}_\tau. \quad (6.1)$$

If $\sigma \leq \tau$, then $\{ \sigma \leq \tau \} = \Omega$, and we get $\mathcal{F}_\sigma \subset \mathcal{F}_\tau$ from (6.1). So we proved (v). Since $\sigma \wedge \tau \leq \sigma, \tau$, by (v) we get $\mathcal{F}_\sigma \wedge \tau \subset \mathcal{F}_\sigma \cap \mathcal{F}_\tau$. On the other hand, if $A \in \mathcal{F}_\sigma \cap \mathcal{F}_\tau$, then from

$$A \cap \{ \sigma \wedge \tau \leq t \} = (A \cap \{ \sigma \leq t \}) \cup (A \cap \{ \tau \leq t \}) \in \mathcal{F}_t, \quad t \in T,$$

we get $A \in \mathcal{F}_\sigma \wedge \tau$. So $\mathcal{F}_\sigma \cap \mathcal{F}_\tau \subset \mathcal{F}_\sigma \wedge \tau$. Thus, $\mathcal{F}_\sigma \wedge \tau = \mathcal{F}_\sigma \cap \mathcal{F}_\tau$. From (6.1) we get $\mathcal{F}_\sigma \cap \{ \sigma \leq \tau \} \subset \mathcal{F}_\sigma \cap \mathcal{F}_\tau = \mathcal{F}_\sigma \wedge \tau$, which is (ii).

Taking $A = \Omega \in \mathcal{F}_\sigma$ in (6.1), we get $\{ \sigma \leq \tau \} \in \mathcal{F}_\sigma \cap \mathcal{F}_\tau$. Swapping $\sigma$ and $\tau$, we get $\{ \sigma < \tau \} = \{ \tau \leq \sigma \} \wedge \{ \sigma \leq \tau \} \subset \mathcal{F}_\sigma \cap \mathcal{F}_\tau$. Thus, $\{ \sigma = \tau \} = \{ \sigma \leq \tau \} \wedge \{ \sigma < \tau \} \subset \mathcal{F}_\sigma \cap \mathcal{F}_\tau$. So we get (iv).

Since by (ii) $\mathcal{F}_\sigma \cap \{ \sigma \leq \tau \} \subset \mathcal{F}_\tau$, and by (iv) $\{ \sigma = \tau \} \in \mathcal{F}_\sigma \cap \mathcal{F}_\tau$, we get $\mathcal{F}_\sigma \cap \{ \sigma = \tau \} \subset \mathcal{F}_\tau \cap \{ \sigma = \tau \}$. Swapping $\sigma$ and $\tau$, we get $\mathcal{F}_\tau \cap \{ \sigma = \tau \} \subset \mathcal{F}_\sigma \cap \{ \sigma = \tau \}$. So (iii) holds.

Finally, since $\tau$ takes values in $T \cup \{ \sup T \}$, to prove (i) that $\tau$ is $\mathcal{F}_\tau$-measurable, it suffices to show that for any $t \in T$, $\{ \tau \leq t \} \subset \mathcal{F}_\tau$. This follows from (iv) since any deterministic time $t$ is an $\mathcal{F}$-stopping time. \hfill $\square$

Suppose now $T = \mathbb{R}_+ = [0, \infty)$. For a filtration $\mathcal{F}$ on $\mathbb{R}_+$, we define a new filtration $\mathcal{F}^+$ by $\mathcal{F}^+_t = \bigcap_{u > t} \mathcal{F}_u$, $t \geq 0$. We understand $\mathcal{F}^+_t$ as the knowledge at an infinitesimal time after $t$. It is clear that for $0 \leq t < u$, $\mathcal{F}_t \subset \mathcal{F}^+_t \subset \mathcal{F}_u$. We may not have $\mathcal{F}_t = \mathcal{F}^+_t$. 

71
Example. Let $\Omega$ be the space left-continuous $\mathbb{Z}_+$-valued increasing functions defined on $\mathbb{R}_+$ with initial value 0. For $t \geq 0$, let $\pi_t : \Omega \to \mathbb{Z}_+$ be the map $\omega \mapsto \omega(t)$. Let $\mathcal{F} = (\mathcal{F}_t)_{t \geq 0}$ be the filtration such that $\mathcal{F}_t = \sigma(\pi_s : 0 \leq s \leq t)$. Fix $t_0 \geq 0$. Let $A_{t_0}$ denote the set of $\omega \in \Omega$ which are continuous at $t_0$. Then $A_{t_0} \in \mathcal{F}_{t_0}^+ \setminus \mathcal{F}_{t_0}^-$. In fact, $A_{t_0} = \{ \pi_{t_0}^+ = \pi_{t_0}^- \}$, where $

$π_{t_0}^+(ω) := \lim_{t \downarrow t_0} \omega(t)$. For any $t_0 \geq 0$, $\pi_{t_0} \in \mathcal{F}_{t_0} \subset \mathcal{F}_{t_0}^+$. For any $u > t_0$, we may pick a sequence $(t_n)$ in $(t_0, u]$ with $t_n \downarrow t_0$. Then $\pi_{t_0}^+ = \lim_{n \to \infty} \pi_{t_n} \in \mathcal{F}_{t_0}^+$. Since this holds for any $u > t_0$, $\pi_{t_0}^+ \in \bigcap_{u > t_0} \mathcal{F}_u = \mathcal{F}_{t_0}^+$. Thus, $A_{t_0} = \{ \pi_{t_0}^+ = \pi_{t_0}^- \} \in \mathcal{F}_{t_0}$.

Next, we show that $A_{t_0} \notin \mathcal{F}_{t_0}$. We define an equivalence relation "$\equiv t_0$" on $\Omega$ such that $\omega_1 \equiv t_0 \omega_2$ iff $\omega_1$ and $\omega_2$ agree on $[0, t_0]$. Let $\mathcal{G}_{t_0}$ be the family of all subsets of $\Omega$ which are unions of the equivalence classes w.r.t. $\equiv t_0$. Then $\mathcal{G}_{t_0}$ is a $\sigma$-algebra, and $\pi_t \in \mathcal{G}_{t_0}$ for $0 \leq t \leq t_0$. Thus, $\mathcal{F}_{t_0} \subset \mathcal{G}_{t_0}$. We see that $A_{t_0} \notin \mathcal{G}_{t_0}$ because for any $\omega_1 \in A_{t_0}$, we may define $\omega_2 \in \Omega \setminus A_{t_0}$ by $\omega_2(t) = \omega_1(t)$ for $0 \leq t \leq t_0$ and $\omega_2(t) = \omega_1(t) + 1$ for $t > t_0$. Thus, $A_{t_0} \notin \mathcal{G}_{t_0}$.

We say that $\mathcal{F}$ is right-continuous if $\mathcal{F}^+ = \mathcal{F}$. This means that the knowledge at time $t$ is the same as the knowledge at the time $t + o(1)$. In particular, $\mathcal{F}^+$ is right-continuous because

$$(\mathcal{F}^+)_t = \bigcap_{u > t} \mathcal{F}_u = \bigcap_{u > t} \bigcap_{v > u} \mathcal{F}_v = \bigcap_{v > t} \mathcal{F}_v = \mathcal{F}_t^+.$$\n
We call $\mathcal{F}^+$ the right-continuation of $\mathcal{F}$. A random time $\tau : \Omega \to [0, \infty]$ is called a weak $\mathcal{F}$-stopping time if for any $t > 0$, $\{ \tau < t \} \in \mathcal{F}_t$. In this case, for any $h > 0$, $\tau + h$ is a $\mathcal{F}$-stopping time because for any $t \geq 0$, when $t < h$, $\{ \tau + h \leq t \} = \emptyset \in \mathcal{F}_t$, and when $t \geq h$, we may take a sequence $(t_n)$ in $(t - h, t)$ with $t_n \downarrow t - h$, and get

$$\{ \tau + h \leq t \} = \{ \tau \leq t - h \} = \bigcap_n \{ \tau < t_n \} \in \mathcal{F}_t,$$

where the last relation holds because $\{ \tau < t_n \} \in \mathcal{F}_{t_n} \subset \mathcal{F}_t$ as $t_n < t$. So for each $h > 0$, we may define a $\sigma$-algebra $\mathcal{F}_{\tau + h}$. If $0 < h_1 < h_2$, from $\tau + h_1 < \tau + h_2$ we get $\mathcal{F}_{\tau + h_1} \subset \mathcal{F}_{\tau + h_2}$. We now define $\mathcal{F}_{\tau +} = \bigcap_{h > 0} \mathcal{F}_{\tau + h}$, which is also a sub-$\sigma$-algebra of $\mathcal{A}$.

Lemma 6.2. A random time $\tau$ is a weak $\mathcal{F}$-stopping time iff it is an $\mathcal{F}^+$-stopping time, in which case $\mathcal{F}_{\tau +} = \mathcal{F}_{\tau +}^+ = \{ A \in \mathcal{A} : A \cap \{ \tau < t \} \in \mathcal{F}_t, \forall t > 0 \}$.

Proof. For any $t \geq 0$ and $u > t$, we note that

$$\{ \tau \leq t \} = \bigcap_{r \in \mathbb{Q}_+ \cap (t, u]} \{ \tau < r \}, \quad \{ \tau < t \} = \bigcup_{r \in \mathbb{Q}_+ \cap (0, t)} \{ \tau \leq r \}.$$

If $A \cap \{ \tau \leq r \} \in \mathcal{F}_r^+$ for all $r \geq 0$, then for $t > 0$,

$$A \cap \{ \tau < t \} = \bigcup_{r \in \mathbb{Q}_+ \cap (0, t)} (A \cap \{ \tau \leq r \}) \in \mathcal{F}_t,$$

72
because for \( r < t \), \( F^+_r \subseteq F_t \). On the other hand, if \( A \cap \{ \tau < r \} \in F_r \) for all \( r > 0 \), then for \( t \geq 0 \) and \( u > t \),

\[
A \cap \{ \tau \leq t \} = \bigcap_{r \in \mathbb{Q}^+ \cap (t,u]} (A \cap \{ \tau < r \}) \in F_u.
\]

Since this holds for any \( u > t \), we get \( A \cap \{ \tau \leq t \} \in F^+_t \). So we have proved the first assertion by taking \( A = \Omega \). For general \( A \in \mathcal{A} \), this shows that \( F^+_\tau = \{ A \in \mathcal{A} : A \cap \{ \tau < t \} \in F_t, \forall t > 0 \} \).

By the definition of \( F_{\tau+h} \), \( A \in F_{\tau+h} \) iff \( A \in F_{\tau+u} \) for each \( h > 0 \), i.e., \( A \cap \{ \tau + h \leq t \} \in F_t \) for each \( t \geq 0 \) and \( h > 0 \). Since \( \{ \tau + h \leq t \} = \emptyset \) when \( h > t \), the above relation is further equivalent to that \( A \cap \{ \tau \leq t - h \} \in F_t \) for any \( t \geq h > 0 \), which by a change of variable \( (s = t - h) \) is equivalent to \( A \cap \{ \tau \leq s \} \in F_s \) for any \( s \geq 0 \) and \( h > 0 \), and hence to \( A \cap \{ \tau \leq s \} \in F^+_s \) for all \( s \geq 0 \), i.e., \( A \in F^+_\tau \). Thus, \( F_{\tau+h} = F^+_\tau \).

Note that if \( \mathcal{F} \) is right-continuous, then a weak \( \mathcal{F} \)-stopping time is an \( \mathcal{F} \)-stopping time, and there is no difference between \( F_{\tau+h} \) and \( F_{\tau} \). Intuitively, \( \tau \) is a weak \( \mathcal{F} \)-stopping time means that \( \tau \) happens using the information of the past and a tiny bit of future.

**Lemma 6.3.** Let \( \tau_1, \tau_2, \ldots \) be weak \( \mathcal{F} \)-stopping times. Then \( \tau := \inf \{ \tau_n \} \) is also a weak \( \mathcal{F} \)-stopping time, and \( F_{\tau} = \bigcap_n F_{\tau_n} \).

**Proof.** We see that for any \( t > 0 \) and \( A \in \mathcal{A} \),

\[
A \cap \{ \tau < t \} = A \cap \bigcup_n \{ \tau_n < t \} = \bigcup_n (A \cap \{ \tau_n < t \}).
\]

Taking \( A = \Omega \), we see that \( \tau \) is a weak \( \mathcal{F} \)-stopping time. By Lemma 6.1, \( F_{\tau} \subseteq \bigcap_n F_{\tau_n} \). If \( A \in \bigcap_n F_{\tau_n} \), then by Lemma 6.2, \( A \cap \{ \tau_n < t \} \in F_t \) for each \( n \), and so by (6.2), \( A \cap \{ \tau < t \} \in F_t \), which implies that \( A \in F_{\tau} \). So we get \( F_{\tau} = \bigcap_n F_{\tau_n} \).

Note that if \( \mathcal{F} \) is right-continuous, this lemma tells us that the infimum of a sequence of \( \mathcal{F} \)-stopping times is an \( \mathcal{F} \)-stopping time. This is not true in general. The lemma below shows another reason that a right-continuous filtration is useful.

If \( T = \mathbb{R}_+ \) or \( \mathbb{Z}_+ \), for a set \( B \subset S \), we may define the hitting time

\[
\tau_B = \inf \{ t \in T, t > 0 : X_t \in B \}.
\]

As usual, we set \( \inf \emptyset = \infty \) by convention. The following result helps us to decide whether \( \tau_B \) is a stopping time.

**Lemma 6.6.** Fix a filtration \( \mathcal{F} \) on \( T = \mathbb{R}_+ \) or \( \mathbb{Z}_+ \), let \( X \) be an \( \mathcal{F} \)-adapted process on \( T \) with values in a measurable space \( S \), and let \( B \subset S \). Then we have the following

(i) If \( T = \mathbb{Z}_+ \) and \( B \) is measurable, \( \tau_B \) is an \( \mathcal{F} \)-stopping time.

(ii) If \( T = \mathbb{R}_+ \), \( S \) is a metric space, \( B \) is closed, and \( X \) is continuous, then \( \tau_B \) is a weak \( \mathcal{F} \)-stopping time.
(iii) If \( T = \mathbb{R}_+ \), \( S \) is a topological space, \( B \) is open, and \( X \) is right- or left-continuous, then \( \tau_B \) is a weak \( \mathcal{F} \)-stopping time.

In particular, in (ii) and (iii), if \( \mathcal{F} \) is right-continuous, then \( \tau_B \) is an \( \mathcal{F} \)-stopping time.

**Proof.** (i) For any \( n \in \mathbb{Z}_+ \),

\[
\{ \tau_B \leq n \} = \bigcup_{k=1}^{n} \{ X_k \in B \} \in \mathcal{F}_n
\]

since for every \( k \leq n \), \( \{ X_k \in B \} \in \mathcal{F}_k \subset \mathcal{F}_n \). So \( \tau_B \) is an \( \mathcal{F} \)-stopping time.

Suppose now \( T = \mathbb{R}_+ \). Let \( t_0 > 0 \). By the definition of \( \tau_B \),

\[
\{ \tau_B < t_0 \} = \bigcup_{0 < t < t_0} \{ X_t \in B \} = \bigcup_{n \in \mathbb{N}} \bigcup_{t \in [\frac{t_0}{n}, (1 - \frac{1}{n})t_0]} \{ X_t \in B \}.
\]

(ii) If \( S \) is a metric space, \( B \) is closed and \( X \) is continuous, then for any \( n \in \mathbb{N} \),

\[
\bigcup_{t \in [\frac{t_0}{n}, (1 - \frac{1}{n})t_0]} \{ X_t \in B \} = \bigcap_{m \in \mathbb{N}} \bigcup_{t \in [\frac{t_0}{m}, (1 - \frac{1}{m})t_0]} \{ \rho(X_t, B) < \frac{1}{m} \}
\]

Thus, for any \( t_0 > 0 \),

\[
\{ \tau_B < t_0 \} = \bigcup_{n \in \mathbb{N}} \bigcap_{m \in \mathbb{N}} \bigcup_{r \in \mathbb{Q} \cap [\frac{t_0}{m}, (1 - \frac{1}{m})t_0]} \{ \rho(X_r, B) < \frac{1}{m} \}.
\]

Since for any \( n, m \in \mathbb{N} \) and \( r \in \mathbb{Q} \cap [\frac{t_0}{n}, (1 - \frac{1}{n})t_0] \), \( \{ \rho(X_r, B) < \frac{1}{m} \} \in \mathcal{F}_r \subset \mathcal{F}_0 \), and the above formula involves only countable union and countable intersection, we set \( \{ \tau_B < t_0 \} \in \mathcal{F}_0 \).

(iii) If \( B \) is open and \( X \) is right-continuous or left-continuous, then for any \( t_0 > 0 \),

\[
\{ \tau_B < t_0 \} = \bigcup_{t \in (0, t_0)} \{ X_t \in B \} = \bigcup_{r \in \mathbb{Q} \cap (0, t_0)} \{ X_r \in B \} \in \mathcal{F}_0.
\]

So we again conclude that \( \tau_B \) is a weak \( \mathcal{F} \)-stopping time. \( \square \)

**Remark.** If we now define \( \tau_B = \inf \{ t \geq 0 : X_t \in B \} \), the above theorem still holds. If \( T = \mathbb{Z}_+ \) and \( \sigma \) is an \( \mathcal{F} \)-stopping time, then \( \tau := \inf \{ t \geq \sigma : X_t \in B \} \) is a stopping time. For the latter statement, we note that for any \( u \in \mathbb{Z}_+ \),

\[
\{ \tau \leq u \} = \bigcup_{0 \leq t \leq u} \{ \sigma \leq t \} \cap \{ X_t \in B \} \in \mathcal{F}_u.
\]
Lemma 6.4 (discrete approximation). For any weak \( F \) stopping time \( \tau \), there exists a sequence of countably valued \( F \)-stopping times \( (\tau_n) \) with \( \tau_n \downarrow \tau \).

Proof. Let \( \tau_n = 2^{-n}[2^n\tau + 1] \). This means that if \( \frac{k}{2^n} \leq \tau < \frac{k+1}{2^n} \) for some \( k \in \mathbb{Z}_{\geq 0} \), then \( \tau_n = \frac{k+1}{2^n} \). Then \( \tau_n \) takes values in \( 2^{-n}\mathbb{N} \) and \( \tau_n \downarrow \tau \). To see that each \( \tau_n \) is an \( F \)-stopping time, we note that for any \( t \geq 0 \), there is \( k_0 \in \mathbb{Z}_{\geq 0} \) such that \( \frac{k_0}{2^n} \leq t < \frac{k_0+1}{2^n} \). Then \( \tau_n \leq t \) iff \( \tau_n \leq \frac{k_0}{2^n} \) iff \( \tau \in \left[ \frac{k}{2^n}, \frac{k+1}{2^n} \right) \) for some \( k \in \mathbb{Z} \) with \( k + 1 \leq k_0 \), which is equivalent to that \( \tau < \frac{k_0}{2^n} \). Since \( \tau \) is a weak \( F \)-stopping time, we get \( \{ \tau_n \leq t \} = \{ \tau < \frac{k_0}{2^n} \} \in \mathcal{F}_{\frac{k_0}{2^n}} \subset \mathcal{F}_t \).

The definition of \( F \)-adaptedness does not imply the joint measurability \( (t, \omega) \mapsto X_t(\omega) \). Now we introduce a stronger concept.

Definition. Let \( F \) be a filtration on \( \mathbb{R}_+ \). An \( S \)-valued process \( X \) on \( \mathbb{R}_+ \) is called \( F \)-progressively measurable or simply progressive if for any \( t_0 \in \mathbb{R}_+ \), the map

\[
\Omega \times [0, t_0] \ni (\omega, t) \mapsto X_t(\omega) \in S
\]

is \( \mathcal{F}_{t_0} \times \mathcal{B}[0, t_0] \)-measurable. A set \( A \in \Omega \times \mathbb{R}_+ \) is called \( F \)-progressive if \( 1_A \) is \( F \)-progressive.

Exercise. Show that (i) an \( F \)-progressive process is \( F \)-adapted; (ii) the class of all \( F \)-progressive sets form a \( \sigma \)-algebra, denoted by \( \mathcal{P} \); and (iii) a stochastic process \( X \) on \( \mathbb{R}_+ \) is \( F \)-progressive iff it is measurable w.r.t. \( \mathcal{P} \).

Lemma. A left- or right-continuous adapted process is progressive.

Proof. Let \( X \) be a left- or right-continuous adapted process. We need to show that for any \( t_0 \geq 0 \), \( (\omega, t) \mapsto X_t(\omega) \) is \( \mathcal{F}_{t_0} \times \mathcal{B}[0, t_0] \)-measurable. Let \( t_0 \geq 0 \). It suffices to construct a sequence of functions \( X^n : \Omega \times [0, t_0] \to S \) such that each \( X^n \) is \( \mathcal{F}_{t_0} \times \mathcal{B}[0, t_0] \)-measurable, and \( X^n \to X \) pointwise on \( \Omega \times [0, t_0] \). If \( X \) is left-continuous, we define \( X^n(\omega, t) = X(\omega, \frac{k}{2^n}t_0) \) if \( \frac{k}{2^n}t_0 \leq t < \frac{k+1}{2^n}t_0 \) for some \( k \in \mathbb{Z} \). If \( X \) is right-continuous, we define \( X^n(\omega, t) = X(\omega, \frac{k+1}{2^n}t_0) \) if \( \frac{k}{2^n}t_0 \leq t < \frac{k+1}{2^n}t_0 \) for some \( k \in \mathbb{Z} \) with \( k + 1 \leq 2^n \) and \( X^n(\omega, t_0) = X(\omega, t_0) \). From the adaptedness of \( X \), we see that in both cases, \( X^n \) is \( \mathcal{F}_{t_0} \times \mathcal{B}[0, t_0] \)-measurable. The pointwise convergence of \( X^n \to X \) follows from the left- or right-continuity of \( X \).

It is useful to have a progressive process for the following reasons.

Lemma 6.5. Fix a filtration with index \( T \). Let \( \tau \) be a \( T \)-valued \( F \)-stopping time. Let \( X \) be an \( F \)-adapted process on \( T \) with values in a measurable space \((S, \mathcal{S})\). Then \( X_\tau : \omega \mapsto X_{\tau(\omega)}(\omega) \) is \( \mathcal{F}_\tau \)-measurable in the following two cases.

(i) \( T \) is countable;

(ii) \( T = \mathbb{R}_+ \) and \( X \) is progressive.
Proof. To prove that \( X_r \) is \( F_r \)-measurable, we need to show that for any \( B \in \mathcal{B}(S) \) and \( t_0 \in T \), \( \{X_r \in B \} \cap \{\tau \leq t_0\} \in F_{t_0} \). Note that 
\[
\{X_r \in B \} \cap \{\tau \leq t_0\} = \{X_{\tau \land t_0} \in B \} \cap \{\tau \leq t_0\};
\]
\[
\{X_{\tau \land t_0} \in B \} = (\{X_r \in B \} \cap \{\tau \leq t_0\}) \cup (\{X_{t_0} \in B \} \cap \{t_0 \leq \tau\}).
\]
Since \( X \) is \( F \)-adapted, \( \{X_r \in B \} \cap \{\tau \leq t_0\} \in F_{t_0} \) iff \( \{X_{\tau \land t_0} \in B \} \in F_{t_0} \). Note that \( \tau \land t_0 \) is an \( F \)-stopping time bounded above by \( t_0 \). So it suffices to show that for any \( F \)-stopping time \( \sigma \) bounded above by \( t_0 \), \( X_\sigma \) is \( F_{t_0} \)-measurable.

(i) Since \( \sigma \) takes values in \( \{t \in T : t \leq t_0\} \), we have 
\[
\{X_\sigma \in B \} = \bigcup_{t \in T : t \leq t_0} (\{X_t \in B \} \cap \{\sigma = t\}) \in F_{t_0}
\]
because \( T \) is countable, and for \( t \in T \) with \( t \leq t_0 \), \( \{X_t \in B \}; \{\sigma = t\} \in F_t \subset F_{t_0} \).

(ii) Now \( \sigma \) takes values in \( [0, t_0] \). The we write \( X_\sigma = X^{t_0} \circ \psi \), where \( X^{t_0} \) is the restriction of \( X \) to \( \Omega \times [0, t_0] \), and \( \psi : \Omega \rightarrow \Omega \times [0, t_0] \) is given by \( \omega \mapsto (\omega, \sigma(\omega)) \). Since \( X \) is progressive, \( X^{t_0} \) is \( F_{t_0} \times B[0, t_0] \)-measurable. In order to show that \( X_\sigma \) is \( F_{t_0} \)-measurable, it suffices to show that \( \psi \) is \( F_{t_0}/(F_{t_0} \times B[0, t_0]) \)-measurable. This holds because for any \( B \in F_{t_0} \) and \( t \in [0, t_0] \), \( \psi^{-1}(B \times [0, t]) = B \cap \{\sigma \leq t\} \in F_{t_0} \). \( \square \)

Let \( \mathbb{P} \) be a probability measure on \( (\Omega, \mathcal{A}) \) and we work on the probability space \( (\Omega, \mathcal{A}, \mathbb{P}) \). For any \( \sigma \)-algebra \( \mathcal{G} \subset \mathcal{A} \), we use \( \mathcal{G} \) to denote the completion of \( \mathcal{G} \), and say that \( \mathcal{G} \) is complete if \( \mathcal{G} = \overline{\mathcal{G}} \). A filtration \( (F_t) \) is called complete if every \( F_t \) is complete. Given any filtration \( \mathcal{F} = (F_t) \), its completion is the filtration \( (\mathcal{F}_t) \). Suppose now \( T = \mathbb{R}_+ \) and \( \mathcal{F} \) is a filtration on \( \mathbb{R}_+ \). We get two filtration extensions of \( \mathcal{F} \): one is its completion \( (\overline{\mathcal{F}}_t) \), the other is its right-continuation \( (\mathcal{F}_t^+) \). The following lemma tells us that the right-continuation of the completion agrees with the completion of the right-continuation.

**Lemma 6.8.** For any filtration \( \mathcal{F} \) on \( \mathbb{R}_+ \), we have 
\[
\overline{\mathcal{F}}_t^+ = \mathcal{F}_t^+, \quad \forall t \geq 0.
\]

**Proof.** Since \( \mathcal{F}_t \subset \overline{\mathcal{F}}_t \) for all \( t \geq 0 \), we have 
\[
\mathcal{F}_t^+ = \bigcap_{u > t} \mathcal{F}_u \subset \bigcap_{u > t} \overline{\mathcal{F}}_u = \overline{\mathcal{F}}_t^+ \quad \forall t \geq 0.
\]

Since every \( \mathcal{F}_t \) is complete, every \( \overline{\mathcal{F}}_t^+ \) is also complete. So \( \overline{\mathcal{F}}_t^+ \subset \mathcal{F}_t^+ \), \( t \geq 0 \).

We now prove the opposite direction. Let \( A \in \mathcal{F}_t^+ \) for some \( t \geq 0 \). Then \( A \in \mathcal{F}_u \) for every \( u > t \). By Lemma 1.25, for each \( u > t \), there is \( A_u \in \mathcal{F}_u \) such that \( \mathbb{P}[A \Delta A_u] = 0 \). Choose \( u_n \downarrow t \) and define \( A' = \lim \sup A_{u_n} \in \mathcal{F}_t^+ \). Then \( \mathbb{P}[A \Delta A'] \leq \sum_n \mathbb{P}[A \Delta A_{u_n}] = 0 \). So \( A \in \overline{\mathcal{F}}_t^+ \). Thus, 
\[
\mathcal{F}_t^+ \subset \overline{\mathcal{F}}_t^+.
\]

The common filtration \( (\overline{\mathcal{F}}_t^+) = (\mathcal{F}_t^+) \) is both complete and right-continuous, and is called the (usual) augmentation of \( \mathcal{F} \).

**Exercise.** Do problems 2 and 4 in Chapter 6.

76
7 Martingales

Definition. Let $\mathcal{F}$ be a filtration with index set $T \subset \mathbb{R}$. Let $X = (X_t)_{t \in T}$ be an $\mathcal{F}$-adapted process of integrable random variables. If for any $s, t \in T$ with $s \leq t$, we have

$$X_s = \mathbb{E}[X_t|\mathcal{F}_s] \text{ a.s.,} \quad (7.1)$$

then we say that $X$ is an $\mathcal{F}$-martingale. If $(7.1)$ holds with “$\leq$” (resp. “$\geq$”) in place of “$=$” for all $s \leq t \in T$, then $X$ is called an $\mathcal{F}$-submartingale (resp. $\mathcal{F}$-supermartingale). If $X = (X^1, \ldots, X^d)$ is a process on $T \in \mathbb{R}^d$, we say that $X$ is an $\mathcal{F}$-vector martingale if for every $1 \leq k \leq d$, $X^k$ is an $\mathcal{F}$-martingale.

Facts: $X$ is an $\mathcal{F}$-martingale iff it is both an $\mathcal{F}$-submartingale and an $\mathcal{F}$-supermartingale; $X$ is an $\mathcal{F}$-supermartingale iff $-X$ is an $\mathcal{F}$-submartingale; and a linear combination of $\mathcal{F}$-martingales is also an $\mathcal{F}$-martingale. We have some freedom to choose the filtration.

Exercise. Prove that if $X$ is an $\mathcal{F}$-martingale (resp. supermartingale or submartingale), then it is also a martingale (resp. supermartingale or submartingale) w.r.t. (i) the completion of $\mathcal{F}$; (ii) the filtration induced by $X$.

Example. Let the filtration $\mathcal{F}$ be given. Let $\zeta$ be an integrable random variable. Let $X_t = \mathbb{E}[\zeta|\mathcal{F}_t], \ t \in T$. Then $X$ is an $\mathcal{F}$-martingale because for any $s \leq t \in T$, by chain rule,

$$\mathbb{E}[X_t|\mathcal{F}_s] = \mathbb{E}[\mathbb{E}[\zeta|\mathcal{F}_t]|\mathcal{F}_s] = \mathbb{E}[\zeta|\mathcal{F}_s] = X_s.$$

By Lemma 5.5, $X$ is uniformly integrable, and so is $L^1$-bounded.

For a process $X$ on $\mathbb{Z}_+$, we define $\Delta X_n = X_n - X_{n-1}, \ n \in \mathbb{N}$.

Exercise. For an $\mathcal{F}$-adapted process $X$ on $\mathbb{Z}_+$, prove that $X$ is an $\mathcal{F}$-martingale (resp. supermartingale or submartingale) iff a.s. $\mathbb{E}[\Delta X_n|\mathcal{F}_{n-1}] = 0$ (resp. $\geq 0$ or $\leq 0$) for all $n \in \mathbb{N}$.

Example. Let $\zeta_1, \zeta_2, \ldots$ be a sequence of independent integrable random variables. For $n \in \mathbb{Z}_+$, let $X_n = \sum_{k=1}^n \zeta_k$ and $\mathcal{F}_n = \sigma(\zeta_k : 1 \leq k \leq n)$. Then $\mathcal{F} = (\mathcal{F}_n)$ is a filtration, and $X = (X_n)$ is $\mathcal{F}$-adapted. For $n \in \mathbb{N}$, since $\Delta X_n = \zeta_n \mathbb{1}_{\mathcal{F}_{n-1}}$, we get a.s. $\mathbb{E}[\Delta X_n|\mathcal{F}_{n-1}] = \mathbb{E}[\zeta_n]$. Thus, $X$ is a martingale (resp. submartingale or supermartingale) if $\mathbb{E}[\zeta_n] = 0$ (resp. $\geq 0$ or $\leq 0$) for all $n \in \mathbb{N}$. If $\text{Law}(\zeta_n) = \frac{1}{2}(\delta_1 + \delta_{-1})$, $X$ is a random walk on $\mathbb{Z}$.

A martingale on $\mathbb{Z}_+$ may be thought of as a gambler’s balance history, who always plays fair games.

Definition. For a filtration $\mathcal{F}$ on $\mathbb{Z}_+$, a process $A = (A_n)_{n \geq 0}$ is called $\mathcal{F}$-predictable if $A_0 \equiv 0$, and for $n \in \mathbb{N}$, $A_n \in \mathcal{F}_{n-1}$.

We use this name because we know the value of $A_n$ at the time $n-1$. Note that a predictable process must be adapted.
Lemma 6.10. For a filtration $\mathcal{F}$ on $\mathbb{Z}_+$, every $\mathcal{F}$-predictable process $X$ can be expressed as the sum $M + A$, where $M$ is an $\mathcal{F}$-martingale and $A$ is $\mathcal{F}$-predictable, and such decomposition is a.s. unique. Moreover $X$ is a submartingale (resp. supermartingale) iff the $A$ in the decomposition is a.s. increasing (resp. decreasing).

The decomposition $X = M + A$ is called the Doob’s decomposition.

**Proof.** Define the process $A$

$$A_n = \sum_{k=1}^{n} \mathbb{E}[\Delta X_k|\mathcal{F}_{k-1}], \quad n \geq 0.$$ 

Then $A_0 = 0$ and for $n \geq 1$, $A_n$ is $\mathcal{F}_{n-1}$-adapted and $\Delta A_n = \mathbb{E}[\Delta X_n|\mathcal{F}_{n-1}]$. So $A$ is $\mathcal{F}$-predictable. Let $M = X - A$. Then $M$ is also an $\mathcal{F}$-adapted process, and for $n \geq 1$, a.s.

$$\mathbb{E}[\Delta M_n|\mathcal{F}_{n-1}] = \mathbb{E}[\Delta X_n - \Delta A_n|\mathcal{F}_{n-1}] = \mathbb{E}[\Delta X_n|\mathcal{F}_{n-1}] - \Delta A_n = 0.$$

So $M$ is an $\mathcal{F}$-martingale. So we get the existence of Doob’s decomposition. Suppose there is another such decomposition $M' + A'$, then $Y := M - M' = A' - A$ is both $\mathcal{F}$-martingale and $\mathcal{F}$-predictable, and has the initial value $Y_0 = 0$. So for any $n \in \mathbb{N}$, a.s. $Y_n = \mathbb{E}[Y_n|\mathcal{F}_{n-1}] = Y_{n-1}$. We then get a.s. $Y_n = 0$ for all $n \in \mathbb{N}$. So we get the a.s. uniqueness of Doob’s decomposition. Moreover, $X$ is a submartingale iff a.s. $\mathbb{E}[\Delta X_n|\mathcal{F}_{n-1}] = \Delta A_n \geq 0$ for each $n \geq 1$, which is equivalent to that a.s. $A_n$ is increasing. Similarly, $X$ is a supermartingale iff a.s. $A_n$ is decreasing. \qed

Lemma 6.11. Let $M$ be a martingale in $\mathbb{R}^d$. Let $f: \mathbb{R}^d \rightarrow \mathbb{R}$ be a convex function. Suppose $X_t = f(M_t)$ is integrable for every $t$. Then $X$ is a submartingale. The statement remains true if $M$ is a submartingale, and $f: \mathbb{R} \rightarrow \mathbb{R}$ is convex and increasing.

**Proof.** The statements follows from Jensen’s inequality for conditional expectation. The first one holds because

$$\mathbb{E}[X_t|\mathcal{F}_s] = \mathbb{E}[f(M_t)|\mathcal{F}_s] \geq f(\mathbb{E}[M_t|\mathcal{F}_s]) = f(M_s) = X_s, \quad s \leq t \in T.$$ 

The second one holds because

$$\mathbb{E}[X_t|\mathcal{F}_s] = \mathbb{E}[f(M_t)|\mathcal{F}_s] \geq f(\mathbb{E}[M_t|\mathcal{F}_s]) \geq f(M_s) = X_s, \quad s \leq t \in T.$$ 

\qed

We say that $X$ is an $L^p$-process if $X_t \in L^p$ for each $t \in T$. We say $X$ is $L^p$-bounded if $\|X_t\|_p$, $t \in T$, is bounded. If $M$ is an $L^p$-martingale, $p \in [1, \infty)$, applying Lemma 6.11 to $f(x) = |x|^p$, we see that $|M|^p$ is a submartingale.

Applying Lemma 6.11 to $f(x) = x \vee 0$, we see that if $X$ is a submartingale, then the process $X_t^+ := X_t \vee 0$, $t \in T$, is also a submartingale.

We say that an $\mathcal{F}$-stopping time $\tau$ is bounded if there is a deterministic time $u \in T$ such that a.s. $\tau \leq u$. The following theorem generalizes the equality $\mathbb{E}[M_t|\mathcal{F}_s] = M_s$ to stopping times.

78
Theorem 6.12 (Optional Stopping Theorem). Let $M$ be a martingale on some index set $T$ with filtration $\mathcal{F}$. Let $\sigma$ and $\tau$ be two $\mathcal{F}$-stopping times taking countably many values. Suppose $\tau$ is bounded. Then $M_\tau$ and $M_{\sigma \land \tau}$ are integrable, and a.s.

$$E[M_\tau | \mathcal{F}_\sigma] = M_{\sigma \land \tau}.$$  

In particular, if a.s. $\sigma \leq \tau$ are both bounded, then a.s. $E[M_\tau | \mathcal{F}_\sigma] = M_\sigma$ and so $E[M_\tau] = E[M_\sigma]$.

Proof. Suppose $u \in T$ satisfies that a.s. $\tau \leq u$. By Lemmas 5.2 (local property) and 6.1 ($\mathcal{F}_\tau$ agrees with $\mathcal{F}_t$ on $\{\tau = t\}$), for any $t \in T$ with $t \leq u$, a.s.

$$E[M_u | \mathcal{F}_\tau] = E[M_u | \mathcal{F}_t] = M_t \text{ on } \{\tau = t\}.$$  

Since $\tau$ takes countably many values, we get a.s. $E[M_u | \mathcal{F}_\tau] = M_\tau$ and so $M_\tau$ is integrable.

Since $\sigma \land \tau$ is also an $\mathcal{F}$-stopping time bounded by $u$ taking countably many values, $M_{\sigma \land \tau}$ is also integrable, and a.s.

$$M_{\sigma \land \tau} = E[M_u | \mathcal{F}_{\sigma \land \tau}] = E[E[M_u | \mathcal{F}_\tau] | \mathcal{F}_{\sigma \land \tau}] = E[M_\tau | \mathcal{F}_{\sigma \land \tau}].$$  

It remains to show that a.s. $E[M_\tau | \mathcal{F}_\sigma] = E[M_\tau | \mathcal{F}_{\sigma \land \tau}]$. Since $\mathcal{F}_\sigma$ agrees with $\mathcal{F}_{\sigma \land \tau}$ on $\{\sigma = \sigma \land \tau\} = \{\sigma \leq \tau\}$, by Lemma 5.2, a.s. $E[M_\tau | \mathcal{F}_\sigma] = E[M_\tau | \mathcal{F}_{\sigma \land \tau}]$ on $\{\sigma \leq \tau\}$. Since $\mathcal{F}_\tau \cap \{\tau \leq \sigma\} \subset \mathcal{F}_\sigma$ and $M_\tau$ is $\mathcal{F}_\tau$-measurable, by Lemma 5.2, a.s. $E[M_\tau | \mathcal{F}_\sigma] = M_\tau$ on $\{\tau \leq \sigma\}$. Since $\mathcal{F}_\tau \cap \{\tau \leq \sigma\} \subset \mathcal{F}_\tau \cap \{\tau \leq \sigma \land \tau\}$, by Lemma 5.2, a.s. $E[M_\tau | \mathcal{F}_\sigma] = M_\tau$ on $\{\tau \leq \sigma\}$.

Combining this with that a.s. $E[M_\tau | \mathcal{F}_\sigma] = E[M_\tau | \mathcal{F}_{\sigma \land \tau}]$ on $\{\sigma \leq \tau\}$, we get a.s. $E[M_\tau | \mathcal{F}_\sigma] = E[M_\tau | \mathcal{F}_{\sigma \land \tau}]$, as desired. $\Box$

Exercise . Prove that if $T = \mathbb{Z}_+$ or finite, and $X$ is a submartingale (resp. supermartingale), then for $\sigma, \tau$ in the theorem, we have a.s. $E[X_\sigma | \mathcal{F}_\sigma] - X_{\sigma \land \tau} \geq 0$ (resp. $\leq 0$). Hint: Use Doob’s decomposition.

Example . The condition on $\tau$ cannot be removed. Suppose $\zeta_1, \zeta_2, \ldots$ is a sequence of i.i.d. random variables with common distribution $\frac{1}{2}(\delta_1 + \delta_{-1})$. For $n \in \mathbb{Z}_+$, let $X_n = \sum_{k=1}^n 2^{k-1} \zeta_k$. Then $X$ is a martingale. Let $\tau = \inf \{n \in \mathbb{N} : \zeta_n = 1\}$. Then $\tau$ is a stopping time, and a.s. takes values in $\mathbb{N}$. In fact,

$$P[\tau = \infty] = P\left[ \bigcap_{N \in \mathbb{N}} \{\tau > N\}\right] = \lim_{N \to \infty} P\left[ \zeta_n = -1, 1 \leq n \leq N\right] = \lim_{N \to \infty} 2^{-N} = 0.$$  

We observe that for any $N \in \mathbb{N}$, when $\tau = N$, $X_\tau = \sum_{k=1}^{N-1} (-1)2^{n-1} + 2^{N-1} = 1$. Thus, $E[X_\tau] = 1$. But since $X_0 = 0$, $E[X_0] = 0 \neq E[X_\tau]$.

This example describes the balance history of a gambler, who bids one dollar on the first day, doubles his bid on every next day, and stops whenever he wins. In reality, a gambler can not win money with this game because he does not have infinite amount of money to bid.

Lemma 6.13 (Martingale Criterion). Let $M$ be an integrable adapted process on some index set $T$ w.r.t. a filtration $\mathcal{F}$. Then $M$ is an $\mathcal{F}$-martingale iff for any two $T$-valued $\mathcal{F}$-stopping times $\sigma$ and $\tau$ taking at most two values, we have $E[M_\sigma] = E[M_\tau]$.
Proof. The only if part follows from Theorem 6.12. For the if part, let \( s < t \in T \). Let \( A \in \mathcal{F}_s \). Then \( \tau := s1_A + t1_{A^c} \) is an \( \mathcal{F} \)-stopping time because for any \( u \in T \), if \( u \geq t \), \( \{ \tau \leq u \} = \Omega \in \mathcal{F}_u \); if \( s \leq u < t \), \( \{ \tau \leq u \} = A \in \mathcal{F}_s \subset \mathcal{F}_u \); and if \( u < s \), \( \{ \tau \leq u \} = \emptyset \in \mathcal{F}_u \). By the assumption, we have
\[
0 = \mathbb{E}M_t - \mathbb{E}M_\tau = \mathbb{E}M_t - \mathbb{E}[1_AM_s] - \mathbb{E}[1_{A^c}M_t] = \mathbb{E}[1_A(M_t - M_s)].
\]
Since this holds for any \( A \in \mathcal{F}_s \), we get a.s. \( \mathbb{E}[M_t - M_s, \mathcal{F}_s] = 0 \). So \( M \) is an \( \mathcal{F} \)-martingale. \( \square \)

**Corollary 6.14** (Martingale Transforms). Let \( M \) be a martingale on some index set \( T \) with filtration \( \mathcal{F} \). Fix a stopping time \( \tau \) that takes countably many values, and let \( \eta \) be a bounded, \( \mathcal{F}_\tau \)-measurable random variable. Then the process \( N_t = \eta(M_t - M_{\tau \wedge t}) \) is again an \( \mathcal{F} \)-martingale.

Taking \( \eta \equiv 1 \), from Corollary 6.14 we see that if \( M \) is an \( \mathcal{F} \)-martingale, and if \( \tau \) is a bounded \( \mathcal{F} \)-stopping time taking countably many values, then the stopped process
\[
M^*_\tau := M_{\tau \wedge t}, \quad t \in T,
\]
is also an \( \mathcal{F} \)-martingale.

**Proof.** Fix \( t \in T \). By Optional Stopping Theorem, \( M_t - M_{\tau \wedge t} \) is \( \mathcal{F}_t \)-measurable and integrable. Since \( \eta \) is bounded, \( N_t \) is also bounded. Since \( N_t = 0 \) on \( \{ t \leq \tau \} \), we may rewrite \( N_t \) as
\[
N_t = 1_{\{ \tau \leq t \}} \eta(M_t - M_{\tau \wedge t}).
\]
Since \( \eta \) is \( \mathcal{F}_\tau \)-measurable, by Lemma 6.1, \( 1_{\{ \tau \leq t \}} \eta \) is \( \mathcal{F}_\tau \)-measurable. So \( N_t \) is \( \mathcal{F}_\tau \)-measurable. Thus, \( N \) is \( \mathcal{F} \)-adapted.

Let \( \sigma \) be any \( T \)-valued \( \mathcal{F} \)-stopping time taking at most two values. By the pull-out property and Optional Stopping Theorem,
\[
\mathbb{E}[N_{\sigma} | \mathcal{F}_\tau] = \eta \mathbb{E}[M_{\sigma} | \mathcal{F}_\tau] - \eta \mathbb{E}[M_{\sigma \wedge \tau} | \mathcal{F}_\tau] = \eta M_{\sigma \wedge \tau} - \eta M_{\sigma \wedge \tau} = 0.
\]
So \( \mathbb{E}[N_{\sigma}] = 0 \). Since this holds for all such \( \sigma \), by Lemma 6.13, \( N \) is an \( \mathcal{F} \)-martingale. \( \square \)

**Proposition 6.15** (maximum inequalities). Let \( X \) be a submartingale on some countable index set \( T \). Then for any \( r \geq 0 \) and \( u \in T \),
\[
\begin{align}
\mathbb{P}[\sup_{t \in T; t \leq u} X_t > r] &\leq \mathbb{E}[1_{\{ \sup_{t \in T; t \leq u} X_t > r \}} X_u] \leq \mathbb{E}X_u^+, \quad (7.2) \\
\mathbb{P}[\sup_{t \in T} |X_t| > r] &\leq 3 \sup_{t \in T} \mathbb{E}|X_t|. \quad (7.3)
\end{align}
\]

**Proof.** We first assume that \( T \) is finite. Then we may assume that \( T = \{0, 1, 2, \ldots, n\} \). Define \( \tau = u \wedge \inf\{ t : X_t > r \} \) and \( B = \{ \max_{t \leq u} X_t > r \} \). Then \( \tau \) is a stopping time bounded by \( u \), and \( B \in \mathcal{F}_\tau \) because for \( t_0 \in T \), if \( t_0 \geq u \), then \( B \cap \{ \tau \leq t_0 \} = B \in \mathcal{F}_u \subset \mathcal{F}_t \); and if \( t_0 < u \), then \( B \cap \{ \tau \leq t_0 \} = \{ \max_{t \leq u} X_t > r \} \in \mathcal{F}_t \). By Optional Stopping Theorem, \( \mathbb{E}[X_u | \mathcal{F}_\tau] \geq X_\tau \).
Since \( X_\tau > r \) on \( B \) and \( X_u^+ = X_u \vee 0 \geq 1_B X_u \), we get
\[
\mathbb{E}X_u^+ \geq \mathbb{E}[1_B X_u] \geq \mathbb{E}[1_B X_\tau] \geq r \mathbb{P}B.
\]
80
which proves (7.2) in the case that $T$ is finite.

Let $M+A$ be the Doob decomposition of $X$. Then $A$ is non-negative and increasing. So $M \leq X$. Applying (7.2) to $-M$, which is a martingale and hence a submartingale, we get

\[
\begin{align*}
  r \mathbb{P}\left[ \min_{t \in T; t \leq u} X_t < -r \right] &\leq r \mathbb{P}\left[ \min_{t \in T; t \leq u} M_t < -r \right] = r \mathbb{P}\left[ \sup_{t \in T; t \leq u} (-M_t) > r \right] \\
  \leq \mathbb{E}[(-M_u)^+] &\leq \mathbb{E}[-M_u] \leq \mathbb{E}[X_u^+] - \mathbb{E}[X_0] = \mathbb{E}[X^+_u] - \mathbb{E}[X_0] \leq \mathbb{E}[\|X_u\|] + \mathbb{E}[\|X_0\|].
\end{align*}
\]

Since \( \{\max_{t \leq u} |X_t| > r\} = \{\max_{t \leq u} X_t > r\} \cup \{\min_{t \leq u} X_t < -r\} \), combining the above formula with (7.2) and taking supremum over $u \in T$ proves (7.3) in the case that $T$ is finite.

For a countable index set $T$, there is an increasing sequence of finite index sets $T_n$ such that $T = \bigcup T_n$ and $u \in T_n$ for each $n$. From the last paragraph, for each $n \in \mathbb{N}$,

\[
  r \mathbb{P}\left[ \sup_{t \in T_n; t \leq u} X_t > r \right] \leq 3 \sup_{t \in T_n} \mathbb{E}|X_t|. 
\]

We have \( \sup_{t \in T; t \leq u} X_t = \lim_n \sup_{t \in T_n; t \leq u} X_t \), so \( 1\{\sup_{t \in T_n; t \leq u} X_t > r\} \rightarrow 1\{\sup_{t \in T; t \leq u} X_t > r\} \) and \( 1\{\sup_{t \in T_n; t \leq u} |X_t| > r\} \rightarrow 1\{\sup_{t \in T; t \leq u} |X_t| > r\} \). By sending $n \rightarrow \infty$ in (7.4) and (7.3) and using DCT, we get (7.2) in the general case.

For a process $X$ on some index set $T$, we define the process $X^* = (X^*_t)_{t \in T}$ by

\[
X^*_t = \sup_{s \in T; s \leq t} |X_s|, \quad t \in T.
\]

Let $X^*_* = \sup_{t \in T} |X_t|$.

**Proposition 6.16** (Doob’s norm inequality). Let $M$ be a martingale on some countable index set $T$. Let $p, q > 1$ satisfy $p^{-1} + q^{-1} = 1$. Then

\[
\|M^*_t\|_p \leq q \|M_t\|_p, \quad t \in T.
\]

**Proof.** If \( \|M_t\|_p = \infty \), the inequality is trivial. If \( \|M_t\| = 0 \), the for any $s \in T$ with $s \leq t$, a.s. $M_s = \mathbb{E}[M_t | F_s] = 0$. Since $T$ is countable, we get a.s. $M^*_t = 0$. The inequality is also trivial.

Now assume $0 < \|M_t\|_p < \infty$. Applying Proposition 6.15 to the submartingale $|M|$, we get for any $r > 0$,

\[
r \mathbb{P}[M^*_t > r] \leq \mathbb{E}[1\{M^*_t > r\}|M_t|].
\]

Note that \( q = \frac{p}{p-1} \). By Lemma 2.4 and Hölder’s inequality,

\[
\|M^*_t\|_p^p = \mathbb{E}(M^*_t)^p = p \int_0^\infty \mathbb{P}[M^*_t > r] r^{p-1} dr \leq p \int_0^\infty \mathbb{E}[1\{M^*_t > r\}|M_t]|M_t|r^{p-2} dr
\]

\[
= p \mathbb{E}\left[|M_t| \int_0^{M^*_t} r^{p-2} dr\right] = q \mathbb{E}[|M_t| (M^*_t)^{p-1}] \leq q \|M_t\|_p (M^*_t)^{p-1} \|q = q \|M_t\|_p \|M^*_t\|_p^{p-1}.
\]

Let both sides be divided by $\|M^*_t\|_p^{p-1}$, we get the inequality again. \( \square \)
Definition. For a real valued process $X$ on $T$, and $a < b \in \mathbb{R}$, an $[a,b]$-upcrossing interval of $X$ is $[s,t]$ such that $s < t \in T$, $X_s \leq a$ and $X_t \geq b$. For $t \in T$, the number of $[a,b]$-upcrossings of $X$ up to $t$, denoted by $N^b_a(t)$, is the supremum of $n \in \mathbb{Z}_+$ such that there exist $n$ mutually disjoint $[a,b]$-upcrossing intervals of $X$ contained in $(-\infty,t]$. This number could be 0 or $\infty$.

Lemma 6.17 (upcrossing inequality). Let $X$ be a submartingale on a countable index set $T$. Then

$$
\mathbb{E}N^b_a(t_0) \leq \frac{\mathbb{E}[(X_{t_0} - a) \vee 0]}{b - a}, \quad t_0 \in T, \quad a < b \in \mathbb{R}.
$$

Proof. Let $Y_t = (X_t - a) \vee 0$. By Lemma 6.11, $Y$ is a submartingale. We see that $[s,t]$ is an $[a,b]$-upcrossing of $X$ iff $[s,t]$ is an $[0,b-a]$-upcrossing of $Y$. Thus, we may assume that $X \geq 0$ and $a = 0$. First assume that $T$ is finite. Then we may assume that $T = \{0,1,\ldots,N\}$. In the end we will use the idea in the proof of Proposition 6.15 to extend the result to the general $T$.

Define $\tau_0 = 0$,

$$
\sigma_n = t_0 \land \inf\{t \geq \tau_{n-1} : X_t = 0\}, \quad \tau_n = t_0 \land \inf\{t \geq \sigma_n : X_t \geq b\}, \quad n \in \mathbb{N}.
$$

Then all $\sigma_n$ and $\tau_n$ are stopping times satisfying $\tau_0 \leq \sigma_1 \leq \tau_1 \leq \cdots \leq \tau_0$; if $\sigma_n < t_0$, $X_{\sigma_n} = 0$; if $\tau_n < t_0$, $X_{\tau_n} \geq b$; and $N^b_a(t_0)$ is the biggest $n$ such that $\sigma_n < t_0$ and $X_{\tau_n} \geq b$ (*).

Fix $n_0 \in \mathbb{N}$. Since $X$ is a submartingale and $X \geq 0$, we have

$$
\mathbb{E}[X_{t_0}] \geq \mathbb{E}[X_{\tau_{n_0}}] \geq \mathbb{E}[X_{\tau_{n_0}}] - \mathbb{E}[X_{\tau_0}] = \sum_{k=1}^{n_0} (\mathbb{E}[X_{\tau_k}] - \mathbb{E}[X_{\tau_k}]) = \sum_{k=1}^{n_0} (\mathbb{E}[X_{\tau_k} - \sigma_k])
$$

$$
\geq \sum_{k=1}^{n_0} (\mathbb{E}[X_{\tau_k}] - \mathbb{E}[X_{\sigma_k}]) = \sum_{k=1}^{n_0} \mathbb{E}[X_{\tau_k} - X_{\sigma_k}].
$$

We have $X_{\tau_k} \geq X_{\sigma_k}$ for each $k$ because if $\sigma_k = t_0$, then $X_{\tau_k} = X_{t_0} = X_{\sigma_k}$, and if $\sigma_k = t_0$, then $X_{\sigma_k} = 0 \leq X_{\tau_k}$. If $N^b_a(t_0) \geq k$, then $X_{\tau_k} = 0$ and $X_{\tau_k} \geq b$. So we have

$$
\mathbb{E}[X_{t_0}] \geq \sum_{k=1}^{n_0} \mathbb{E}[1_{N^b_a(t_0) \geq k}] b = b \sum_{k=1}^{n_0} \mathbb{P}[N^b_a(t_0) \geq k].
$$

Since this inequality holds for any $n_0 \in \mathbb{N}$, we get $\mathbb{E}[X_{t_0}] \geq b \sum_{k=1}^{\infty} \mathbb{P}[N^b_a(t_0) \geq k] = b \mathbb{E}[N^b_a(t_0)]$. So we finish the proof in the case that $T$ is finite.

For the general case, we may find an increasing sequence of finite sets $T_n$ such that $t_0 \in T_n$ for each $n$ and $T = \bigcup_{n} T_n$. Let $N^b_a(T_n,t_0)$ denote the number of $[a,b]$-upcrossings of $X$ on $T_n$ up to $t_0$. Then $N^b_a(T_n,t_0) \uparrow N^b_a(t_0)$, and we have the upper bound for each $N^b_a(T_n,t_0)$, which does not depend on $n$. Then we finish the proof in the general case by letting $n \to \infty$. \qed

Exercise. Prove the statement (*) in the proof of Lemma 6.17.

Theorem 6.18 (Doob’s regularization theorem). Let $X$ be an $L^1$-bounded submartingale on some index set $T$. Then for every monotone sequence $(t_n)$ in $T$, a.s. $X_{t_n}$ converges.

82
Proof. Since the statement concerns only on \(X_{t_n}, n \in \mathbb{N}\), we may assume that \(T = \{t_n : n \in \mathbb{N}\}\).

So \(T\) is countable. Suppose \(\|X_t\|_1 \leq m\) for all \(t \in T\). By Proposition 6.15, for any \(r > 0\), \(\mathbb{P}[\sup_{t \in T} |X_t| > r] \leq \frac{m}{r}\), which implies that a.s. \(X\) is bounded on \(T\). Let the exceptional event be \(E_0\). By Lemma 6.17, for any \(t \in T\) and \(a, b \in \mathbb{Q}\) with \(a < b\),

\[
\mathbb{E}N^h_a(t) \leq \mathbb{E}[(X_t - a) \vee 0] \leq \frac{\|X_t - a\|_1}{b - a} \leq \frac{\|X_t\|_1 + |a|}{b - a} \leq \frac{m + |a|}{b - a}.
\]

Let \(T \ni t_n \uparrow \sup T\), we get \(\mathbb{E}N^h_a(\sup T) \leq \frac{m + |a|}{b - a}\). So a.s. \(N^h_a(\sup T) < \infty\). Let the exceptional event be \(E_{a,b}\). For an increasing or decreasing sequence \((t_n)\) in \(T\), if \((X_{t_n})\) diverges then either \(X\) is unbounded or \(\limsup X_{t_n} > \liminf X_{t_n}\). In the latter case, we can find \(a, b \in \mathbb{Q}\) such that \(\limsup X_{t_n} > b > a > \liminf X_{t_n}\), which implies that there are infinitely many \([a, b]\)-upcrossings of \(X\). Thus,

\[
\{X_{t_n}\text{ diverges}\} \subset E_0 \cup \bigcup_{a < b \in \mathbb{Q}} E_{a,b}.
\]

Since the RHS is a null set, we get a.s. \(X_{t_n}\) converges. \(\Box\)

A martingale \(M\) is said to be closed if \(u = \sup T \in T\). In this case, clearly \(M_t = \mathbb{E}[M_u|\mathcal{F}_t]\) for all \(t \in T\). If \(\sup T \notin T\), we say that \(M\) is closable if it can be extended to a martingale on \(\bar{T} = T \cup \{\sup T\}\). If \(M_t = \mathbb{E}[\zeta|\mathcal{F}_t]\) for some \(\zeta \in L^1\), we may clearly choose \(M_u = \zeta\).

**Theorem 6.21.** For a martingale \(M\) on an index set \(T\) such that \(\sup T \notin T\), the following are equivalent:

(i) \(M\) is uniformly integrable, i.e., \(\{M_t : t \in T\}\) is uniformly integrable;

(ii) \(M\) is closeable, i.e., there is \(\zeta \in L^1\) such that \(M_t = \mathbb{E}[\zeta|\mathcal{F}_t]\) for all \(t \in T\);

(iii) \(M\) is convergent at \(\sup T\), i.e., as \(T \ni t \uparrow \sup T\), \(M_t\) converges in \(L^1\).

Proof. By Lemma 5.5, (ii) implies (i). Now assume (i). Then \(M\) is \(L^1\)-bounded. If \(T \ni t_n \uparrow \sup T\), by Theorem 6.18, a.s. \(M_{t_n}\) converges. By Proposition 3.12, \(M_{t_n}\) converges in \(L^1\). Since this holds for any such sequence \((t_n)\), the limit does not depend on \((t_n)\). In fact, for any two increasing sequences \((t_n)\) and \((t'_n)\) in \(T\) that tend to \(\sup T\) we may construct an increasing sequence \((t''_n)\) in \(T\) tending to \(\sup T\) such that \((t_n)\) and \((t'_n)\) are both subsequences of \((t''_n)\). Then \(M_{t''_n}\) converges in \(L^1\), which is the common limit of \((M_{t_n})\) and \((M_{t'_n})\). So we conclude that \(M_t\) converges in \(L^1\) as \(T \ni t \uparrow \sup T\). Finally, assume (iii). Let \(\zeta \in L^1\) be the \(L^1\)-limit of \(M_t\) as \(t \uparrow T\). For any \(u, t \in T\) with \(u \geq t\), we have \(\mathbb{E}[M_u|\mathcal{F}_t] = M_t\). Since \(M_u \to \zeta\) in \(L^1\) as \(u \to \sup T\), by \(L^1\)-contractivity of \(\mathbb{E}F_t\), we get \(\mathbb{E}[\zeta|\mathcal{F}_t] = M_t\). So \(M\) is closeable. \(\Box\)

**Corollary 6.22.** Let \(p \in (1, \infty)\). Let \(M\) be a martingale on an index set \(T\) not bounded above. Then \(M\) is \(L^p\)-bounded iff \(M_t\) converges in \(L^p\) as \(T \ni t \to \infty\).
For such a process any A

Let extend the theory to martingales on \( \mathbb{R} \) bounded. By Theorems 6.18 and Lemma 3.12, \( T \ni a.s. \) constant. Since \( E \) be the limit.

By Theorem 6.23, \( M_{t_n} \) converges a.s. and in \( L^1 \). If \( (t_n) \) is increasing, the limit is \( E[\zeta | \sigma_n, T] \). If \( (t_n) \) is decreasing, the limit is \( E[\zeta | \bigcap_n \mathcal{F}_{t_n}] \).

Proof. Let \( M_t = E[\zeta | \mathcal{F}_t], t \in T \). Then \( M \) is a uniformly integrable \( \mathcal{F} \)-martingale, and so is \( L^1 \)-bounded. By Theorems 6.18 and Lemma 3.12, \( M_{t_n} \) converges a.s. and in \( L^1 \). Let \( \eta = \lim sup M_{t_n} \) be the limit.

If \( (t_n) \) is increasing, then \( \eta \) is \( \bigvee_n \mathcal{F}_{t_n} \)-measurable. Let \( A \in \bigcup_n \mathcal{F}_{t_n} \). Then there is \( n_0 \) such that for \( n \geq n_0, A \in \mathcal{F}_{t_n} \), which implies that \( E[1_A \zeta] = E[1_A M_{t_n}] \). Since \( M_{t_n} \to \eta \) in \( L^1 \), we get \( E[1_A \zeta] = E[1_A \eta] \). By a monotone class argument, we then conclude that this equality holds for any \( A \in \bigvee_n \mathcal{F}_{t_n} \). So we get \( \eta = E[\zeta | \bigvee_n \mathcal{F}_{t_n}] \).

If \( (t_n) \) is decreasing, then \( \eta \) is \( \bigcap_n \mathcal{F}_{t_n} \)-measurable. Let \( A \in \bigcap_n \mathcal{F}_{t_n} \). Then for any \( n \), \( E[1_A \zeta] = E[1_A M_{t_n}] \). Since \( M_{t_n} \to \eta \) in \( L^1 \), we get \( E[1_A \zeta] = E[1_A \eta] \). So we get \( \eta = E[\zeta | \bigcap_n \mathcal{F}_{t_n}] \).

Theorem 6.23. Let \( \zeta \in L^1 \). Let \( \mathcal{F} \) be a filtration on \( T \). Let \( (t_n) \) be a monotone sequence in \( T \). Then \( E[\zeta | \mathcal{F}_{t_n}] \) converges a.s. and in \( L^1 \). If \( (t_n) \) is increasing, the limit is \( E[\zeta | \sigma_n, T] \); and if \( (t_n) \) is decreasing, the limit is \( E[\zeta | \bigvee_n \mathcal{F}_{t_n}] \).

Proof. Let \( M_t = E[\zeta | \mathcal{F}_t], t \in T \). Then \( M \) is a uniformly integrable \( \mathcal{F} \)-martingale, and so is \( L^1 \)-bounded. By Theorems 6.18 and Lemma 3.12, \( M_{t_n} \) converges a.s. and in \( L^1 \). Let \( \eta = \lim sup M_{t_n} \) be the limit.

For \( n \in \mathbb{N} \), let \( \mathcal{F}_{-n} = \sigma(S_m : m \geq n) \). Then it is clear that \( \mathcal{F} = (\mathcal{F}_{-n}) \) is a filtration on \( -\mathbb{N} \). Let \( n \in \mathbb{N} \). By the i.i.d. property of \( (\zeta_n) \), for any \( k \leq n \), \( (\zeta_k, S_n, S_{n+1}, \ldots) \) has the same distribution as \( (\zeta_1, S_n, S_{n+1}, \ldots) \). So \( E[\zeta_k | \mathcal{F}_{-n}] = E[\zeta_1 | \mathcal{F}_{-n}], 1 \leq k \leq n \). Thus,

\[
E[\zeta_1 | \mathcal{F}_{-n}] = \frac{1}{n} \sum_{k=1}^{n} E[\zeta_k | \mathcal{F}_{-n}] = \frac{1}{n} E[S_n | \mathcal{F}_{-n}] = \frac{1}{n} S_n.
\]

By Theorem 6.23, \( \frac{1}{n} S_n \) converges a.s. and in \( L^1 \). By Kolmogorov’s zero-one law, the limit is a.s. constant. Since \( E[\frac{1}{n} S_n] = E[\zeta_1] \) for every \( n \), the constant must be \( E[\zeta_1] \).

Most of the theorems we studied require that the index set \( T \) to be countable. In order to extend the theory to martingales on \( \mathbb{R}_+ \), we will assume that the processes are right-continuous. For such a process \( X \), we may use \( X | \mathcal{Q}_+ \) to recover the whole \( X \).

Lemma 6.28. Let \( X \) be a submartingale on an index set \( \{t_\infty, \ldots, t_2, t_1\} \) with \( t_1 > t_2 > \ldots > t_\infty \). Then \( (X_{t_n}) \) is uniformly integrable and converges a.s. and in \( L^1 \).

Proof. For every \( n \in \mathbb{N} \), let \( \alpha_n = E[X_{t_n} | \sigma_{t_{n+1}}] - X_{t_{n+1}} \geq 0 \), which is \( \mathcal{F}_{t_{n+1}} \)-measurable. Then

\[
\sum_n E\alpha_n = \sum_n (E X_{t_n} - E X_{t_{n+1}}) = E X_{t_1} - \lim_n E X_{t_n} \leq E X_{t_1} - E X_{t_\infty} < \infty.
\]
From this inequality, we see that \( \{ \sum_k \alpha_k \} \in \bigcap_n F_n \). Define \( A_{t_n} \), \( n \in \mathbb{N} \), such that \( A_{t_n} = \sum_{k \geq n} \alpha_k \) on \( \{ \sum_k \alpha_k < \infty \} \) and \( A_{t_n} \equiv 0 \) on \( \{ \sum_k \alpha_k = \infty \} \). Then each \( A_{t_n} \) is \( F_{t_n} \)-measurable. Let \( M_{t_n} = X_{t_n} - A_{t_n} \). Then \( M \) is a martingale on \( \{ t_n : n \in \mathbb{N} \} \) because

\[
E[M_{t_n} - M_{t_{n+1}} | F_{t_{n+1}}] = E[X_{t_n} - X_{t_{n+1}} - \alpha_n | F_{t_{n+1}}] = 0.
\]

It is uniformly integrable since it is closable by \( M_{t_1} \). The process \( A \) is also uniformly integrable because \( \sup_n |A_{t_n}| = A_{t_1} \) and \( EA_{t_1} = \sum E\alpha_n < \infty \). So \( \{ X_{t_n} : n \in \mathbb{N} \} \) is uniformly integrable. By the definition of \( A \), \( A_{t_n} \to 0 \). By Theorem 6.18, \( M_{t_n} \) a.s. converges. Thus, a.s. \( X_{t_n} \) converges. By Theorem 3.12, \( X_{t_n} \) converges in \( L^1 \).

**Theorem 6.29.** Let \( X \) be an \( F \)-submartingale on \( \mathbb{R}_+ \). Suppose both \( X \) and \( F \) are right-continuous. Then for any two stopping times \( \sigma, \tau \) with \( \tau \) being bounded, we have a.s.

\[
E[X_{\tau} | F_\sigma] \geq X_{\sigma \wedge \tau}.
\]  

(7.6)

If \( X \) is an \( F \)-supermartingale, then by applying the theorem to \( -X \), we get \( E[X_{\tau} | F_\sigma] \leq X_{\sigma \wedge \tau} \). If \( X \) is an \( F \)-martingale, then since it is both a submartingale and a supermartingale, the equality in (7.6) holds.

**Proof.** For \( n \in \mathbb{N} \), let \( \tau_n = 2^{-n}[2^n \tau + 1] \) and \( \sigma_n = 2^{-n}[2^n \sigma + 1] \). Then \( (\tau_n) \) and \( (\sigma_n) \) are stopping times with \( \tau_n \downarrow \tau \) and \( \sigma_n \downarrow \sigma \). Since each \( \tau_n \) and \( \sigma_n \) take countably many values, by Optional Stopping Theorem we have learned, we have a.s.

\[
E[X_{\tau_n} | F_{\sigma_m}] \geq X_{\tau_n \wedge \sigma_m}, \quad m, n \in \mathbb{N}.
\]  

(7.7)

Fix \( n \in \mathbb{N} \). Since \( F \) is right-continuous, \( F_\sigma = \bigcap_m F_{\sigma_m} \). By Theorem 6.23, as \( m \to \infty \), \( E[X_{\tau_n} | F_{\sigma_m}] \to E[X_{\tau_n} | F_\sigma] \) a.s. and in \( L^1 \). Since \( X \) is right-continuous, \( X_{\tau_n \wedge \sigma_m} \to X_{\tau_n \wedge \sigma} \) as \( m \to \infty \). Sending \( m \to \infty \) in (7.7), we get a.s.

\[
E[X_{\tau_n} | F_\sigma] \geq X_{\tau_n \wedge \sigma}, \quad n \in \mathbb{N}.
\]  

(7.8)

From this inequality, we see that \( (X_0, \ldots, X_{\tau_2}, X_{\tau_1}) \) is a submartingale w.r.t. the filtration \( (F_0, \ldots, F_{\tau_2}, F_{\tau_1}) \). By Lemma 6.28, \( (X_{\tau_n}) \) converges a.s. and in \( L^1 \). Since \( \tau_n \downarrow \tau \), the limit is \( X_\tau \) by the right-continuity of \( X \). Sending \( n \to \infty \) in (7.8), we get (7.6). \( \square \)

Finally, we discuss the existence of a right-continuous version of a sub-martingale on \( \mathbb{R}_+ \). Given a process \( X \) on \( T \), we say that another process \( X' \) on \( T \) is a version of \( X \) if for any \( t \in T \), a.s. \( X'_t = X_t \). This in general is weaker than the condition that a.s. \( X'_t = X_t \) for any \( t \in T \), in which case we say that \( X \) and \( X' \) are indistinguishable. Suppose \( F \) is a complete filtration on \( T \). If \( X \) is \( F \)-adapted, then any version of \( X \) is also \( F \)-adapted. If \( X \) is an \( F \)-martingale (or submartingale), then any version of \( X \) is also an \( F \)-martingale (or submartingale).

A process \( X \) on \( \mathbb{R}_+ \) is called rcll (right-continuous with left-hand limits, also called Càdlàg) if for every \( \omega \in \Omega \) and \( t_0 > 0 \), \( \lim_{t \downarrow t_0} X_t(\omega) = X_{t_0}(\omega) \), and when \( t_0 > 0 \), \( \lim_{t \uparrow t_0} X_t(\omega) \) converges.
**Theorem 6.27.** Let $\mathcal{F}$ be a right-continuous and complete filtration on $\mathbb{R}_+$. Let $X$ be an $\mathcal{F}$-submartingale. Suppose $t \mapsto \mathbb{E}X_t$ is right-continuous. Then $X$ has an rcll version. In particular, if $X$ is an $\mathcal{F}$-martingale, then an rcll version of $X$ exists.

**Proof.** Let $Y = X|_{\mathbb{Q}_+}$. By Proposition 6.15, for any $n \in \mathbb{N}$, a.s. $Y$ is bounded on $\mathbb{Q}_+ \cap [0, n]$. By upcrossing inequality (Lemma 6.17), for any $n \in \mathbb{N}$ and $a < b \in \mathbb{Q}$, the number of $[a, b]$-upcrossings of $Y$ before $n$ is a.s. finite. Thus there is $N \in \mathcal{A}$ with $\mathbb{P}N = 0$ such that for $\omega \in N^c$, for any $n \in \mathbb{N}$ and $a < b \in \mathbb{Q}$, $Y_t(\omega)$ is bounded on $\mathbb{Q}_+ \cap [0, t]$, and $\mathbb{Q}_+ \ni t \mapsto Y_t(\omega)$ has finitely many $[a, b]$-upcrossings before $n$. Thus, for $\omega \in \Omega \setminus N$, and any bounded increasing or decreasing sequence $(t_n)$ in $\mathbb{Q}_+$, $Y_{t_n}(\omega)$ converges. Let $\omega \in \Omega \setminus N$ and $t \in \mathbb{R}_+$. We may choose a sequence $(t_n)$ in $\mathbb{Q}_+$ with $t_n \downarrow t$. Then $\lim Y_{t_n}(\omega)$ converges. By a limit argument we see that the limit does not depend on $(t_n)$. Thus, $\lim_{\mathbb{Q}_+ \ni t_0} Y_t$ converges. Define a process $Z$ on $\mathbb{R}_+$ such that if $\omega \in \Omega \setminus N$, then for any $t_0 \in \mathbb{R}_+$, we define $Z_{t_0}(\omega) = \lim_{\mathbb{Q}_+ \ni t_0} Y_t(\omega)$; and if $\omega \in N$, then $Z_t(\omega) = 0$ for all $t \in \mathbb{R}_+$. It is clear that $Z$ is an rcll. (Exercise)

Since $\mathcal{F}$ is right-continuous and complete, and $\mathbb{P}N = 0$, $Z$ is $\mathcal{F}$-adapted. Let $t \geq 0$. Let $(t_n)$ be a sequence in $\mathbb{Q}_+$ with $t_n \downarrow t$. By Lemma 6.28, $(Y_{t_n})$ converges in $L^1$ to $Z_t$. Since a.s. $\mathbb{E}[Y_{t_n}|\mathcal{F}_t] = \mathbb{E}[X_{t_n}|\mathcal{F}_t] \geq X_t$, we get a.s. $Z_t = \mathbb{E}[Z_t|\mathcal{F}_t] \geq X_t$. By the right-continuity of $\mathbb{E}X_t$, $\mathbb{E}Z_t = \lim \mathbb{E}Y_{t_n} = \lim \mathbb{E}X_{t_n} = \mathbb{E}X_t$. This together with a.s. $Z_t \geq X_t$ implies a.s. $Z_t = X_t$. So $Z$ is a version of $X$. \hfill $\square$

**Example.** The most important example of continuous martingale is Brownian motion, which is also a Markov process. We will learn its construction in the next chapter.

**Example.** Suppose $X_0, X_1, X_2, \ldots$ is a random walk on $\mathbb{Z}$. We extend $X$ to a process $Y$ on $\mathbb{R}_+$ such that $Y_t = X_{\lfloor t \rfloor}$ for $t \geq 0$. Then $Y$ is a right-continuous martingale on $\mathbb{R}_+$, and has no continuous version.

**Exercise.** Do problems 13, 15, 17, 19 of Chapter 6.

### 8 Markov Processes

**Definition.** Let $(S, \mathcal{S})$ be a Borel space. An $S$-valued $\mathcal{F}$-adapted process $X$ on $T$ is called an $\mathcal{F}$-Markov process if for any $u \geq t \in T$, a.s.

$$\text{Law}(X_u|\mathcal{F}_t) = \text{Law}(X_u|X_t).$$

By Theorem 5.3, the Markov property is equivalent to that, for any $A \in \mathcal{S}$, a.s.

$$\mathbb{P}[X_u \in A|\mathcal{F}_t] = \mathbb{P}[X_u \in A|X_t].$$

By Proposition 5.6, the Markov property is equivalent to that

$$X_u \perp_{\mathcal{F}_t} X_t, \quad \forall u \geq t \in T.$$
Exercise. Prove that if $X$ is an $\mathcal{F}$-Markov process, then it is also a Markov process w.r.t. (i) the completion of $\mathcal{F}$; and (ii) the filtration induced by $\mathcal{F}$.

Lemma 7.1. If $X$ is an $\mathcal{F}$-Markov process on $T$, then for any $t \in T$,

$$\mathcal{F}_t \|_{X_t} \{ X_u : u \geq t \},$$

and

$$\{ X_s : s \leq t \} \|_{X_t} \{ X_u : u \geq t \}.$$

The last relation means that given the present, the future is independent of the past.

Proof. Let $t = t_0 \leq t_1 \leq \cdots \in T$. Then $\text{Law}(X_{t_{n+1}} | \mathcal{F}_{t_n}) = \text{Law}(X_{t_{n+1}} | X_{t_n})$. Since

$$\sigma(X_{t_n}) \subset \sigma(X_{t_0}, \ldots, X_{t_n}) \subset \sigma(\mathcal{F}_t, X_{t_0}, \ldots, X_{t_n}) \subset \mathcal{F}_{t_n},$$

we get $\text{Law}(X_{t_{n+1}} | X_{t_n}) = \text{Law}(X_{t_{n+1}} | X_{t_0}, \ldots, X_{t_n}) = \text{Law}(X_{t_{n+1}} | \mathcal{F}_t, X_{t_0}, \ldots, X_{t_n})$, which implies by Proposition 5.6 that

$$\mathcal{F}_{t_1} \|_{X_{t_0}, X_{t_1}, \ldots, X_{t_n}} X_{t_{n+1}}, \quad n \geq 0,$$

which further implies by Proposition 5.8 that

$$\mathcal{F}_{t_1} \|_{X_{t_0}} X_{t_1}, X_{t_2}, \ldots.$$

By a monotone class argument, we get $\mathcal{F}_t \|_{X_t} \{ X_u : u \geq t \}$. The last formula holds because $X$ is $\mathcal{F}$-adapted. \qed

By Theorem 5.3, for any $t \leq u \in T$, there is a probability kernel $\mu_{t,u}$ from $S$ to $S$ (we now call it a kernel on $S$) such that for any $A \in \mathcal{F}$, a.s.

$$\mathbb{P}[X_u \in A | \mathcal{F}_t] = \mu_{t,u}(X_t, A).$$

Such $\mu_{t,u}$ is $\text{Law}(X_t)$-a.s. unique, and is called a transition kernel. When $t = u$, $\mathbb{P}[X_t \in A | \mathcal{F}_t] = 1_A(X_t) = \delta_{X_t} A$. So we may choose $\mu_{t,t}$ to be $\mu_{t,t}(s, A) = \delta_{s} A$ for $s \in S$ and $A \in \mathcal{F}$. Let $\nu_t = \text{Law}(X_t)$, $t \in T$.

Proposition 7.2. Let $t_0 \leq t_1 \leq \cdots \leq t_n \in T$. We have

$$\text{Law}(X_{t_1}, \ldots, X_{t_n} | \mathcal{F}_{t_0}) = (\mu_{t_0,t_1} \otimes \mu_{t_1,t_2} \otimes \cdots \otimes \mu_{t_{n-1},t_n})(X_{t_0}, \cdot);$$

and

$$\text{Law}(X_{t_1}, \ldots, X_{t_n}) = \nu_{t_0} \mu_{t_0,t_1} \otimes \mu_{t_1,t_2} \otimes \cdots \otimes \mu_{t_{n-1},t_n}.$$

Corollary 7.3. For any $s \leq t \leq u \in T$, $\nu_s \mu_{s,t} = \nu_t$, and $\nu_s$-a.s. $\mu_{s,u} = \mu_{s,t} \mu_{t,u}$.
Recall that for kernels \( \mu_1, \ldots, \mu_n \) on \( S \), \( \mu_1 \otimes \cdots \otimes \mu_n \) is a probability kernel from \( S \) to \( S^n \) such that for \( s_0 \in S \) and \( A \in \mathcal{S}^n \),

\[
(\mu_1 \otimes \cdots \otimes \mu_n)(s_0, A) = \int \mu_1(s_0, ds_1) \int \mu_2(s_1, ds_2) \cdots \int \mu_n(s_{n-1}, ds_n) \mathbf{1}_A(s_1, \ldots, s_n);
\]

and \( \mu_1 \mu_2 \) is a probability kernel from \( S \) to \( S \) defined by \( (\mu_1 \mu_2)(s_0, A) = (\mu_1 \otimes \mu_2)(s_0, S \times A) \) for \( s_0 \in S \) and \( A \in \mathcal{S} \). If, in addition, \( \nu \) is a probability measure on \( S \), then \( \nu \mu_1 \otimes \cdots \otimes \mu_n \) is a probability measure on \( S^n \) such that for \( A \in \mathcal{S}^n \),

\[
(\nu \mu_1 \otimes \cdots \otimes \mu_n)A = \int \nu(ds_0)(\mu_1 \otimes \cdots \otimes \mu_n)(s_0, A).
\]

If \( f : S^n \to \mathbb{R}_+ \) is measurable, then

\[
(\nu \mu_1 \otimes \cdots \otimes \mu_n)f = \int \nu(ds_0) \int \mu_1(s_0, ds_1) \int \mu_2(s_1, ds_2) \cdots \int \mu_n(s_{n-1}, ds_n)f(s_1, \ldots, s_n).
\]

**Exercise.** Prove that for a probability measure \( \nu \) on \( S \) and kernels \( \mu_1, \mu_2, \mu_3 \) on \( S \), we have the associative law: \( (\nu \mu_1)\mu_2 = \nu(\mu_1 \mu_2) \) and \( (\mu_1 \mu_2)\mu_3 = \mu_1(\mu_2 \mu_3) \).

**Proof of Proposition 7.2.** Let \( f : S^n \to \mathbb{R} \) be a bounded measurable function. By Theorem 5.4,

\[
\mathbb{E}[f(X_{t_1}, \ldots, X_{t_n})|\mathcal{F}_{t_{n-1}}] = \int f(X_{t_1}, \ldots, X_{t_{n-1}}, s_n) \text{Law}(X_{t_n}|\mathcal{F}_{t_{n-1}})(ds_n)
\]

\[
= \int \mu_{t_{n-1}, t_n}(X_{t_{n-1}}, ds_n)f(X_{t_1}, \ldots, X_{t_{n-1}}, s_n).
\]

Note that we replace the \( X_{t_n} \) by \( s_n \) and integrate against \( \mu_{t_{n-1}, t_n}(X_{t_{n-1}}, ds_n) \). Since the RHS of the above formula is a bounded measurable function composed with \( X_{t_1}, \ldots, X_{t_{n-1}} \), by conditioning it further on \( \mathcal{F}_{t_{n-2}} \) and using a similar argument, we get

\[
\mathbb{E}[f(X_{t_1}, \ldots, X_{t_n})|\mathcal{F}_{t_{n-2}}] = \int \mu_{t_{n-2}, t_{n-1}}(X_{t_{n-2}}, ds_{n-1}) \int \mu_{t_{n-1}, t_n}(s_{n-1}, ds_n)f(X_{t_1}, \ldots, X_{t_{n-2}}, s_{n-1}, s_n).
\]

Iterating this argument, we get

\[
\mathbb{E}[f(X_{t_1}, \ldots, X_{t_n})|\mathcal{F}_{t_0}] = \int \mu_{t_0, t_1}(X_{t_0}, s_1) \int \mu_{t_1, t_2}(s_1, ds_2) \cdots \int \mu_{t_{n-1}, t_n}(s_{n-1}, ds_n)f(s_1, \ldots, s_n).
\]

Setting \( f = \mathbf{1}_A \) for \( A \in \mathcal{S}^n \), we get \( \boxed{8.1} \). Taking expectation, we then get \( \boxed{8.2} \). \qed
Proof of Corollary 7.3. Taking \( n = 1, t_0 = s \) and \( t_1 = t \) in (8.2), we find that for any \( A \in \mathcal{F} \), \( \nu t A = \text{Law}(X_t)(A) = (\nu s t A) A \). So \( \nu t = \nu s t A \). Taking \( n = 2, t_0 = s, t_1 = t, \) and \( t_2 = u \) in (8.1), we find that for any \( A \in \mathcal{F} \), a.s.

\[
\mu s u (X_s, A) = \text{Law}(X_u | \mathcal{F}_s) (\cdot, A) = \text{Law}(X_t, X_u | \mathcal{F}_s) (\cdot, S \times A)
\]

Thus, a.s. \( \nu s t u = (\mu s t \mu t u) (X_s, \cdot) \), which implies that \( \nu s \text{-a.s.} \mu s u = \mu s t \mu t u \). \( \square \)

We call the equalities \( \mu s u = \mu s t \mu t u, \forall s \leq t \leq u \in T, \) the Chapman-Kolmogorov relation.

Theorem 7.4. Let \((S, \mathcal{S})\) be a Borel space. Let \( T \subset \mathbb{R} \) be an index set such that \( \min T \) exists. Suppose \( \mu s t, s < t \in T, \) is a family of kernels on \( S \) that satisfies the Chapman-Kolmogorov relation. Then for any probability measure \( \nu \) on \( S \), there is an \( S \)-valued Markov process \( X \) on \( T \) with transition kernel \( \mu s t \) and initial distribution \( \text{Law}(X_{\min T}) = \nu \).

Proof. We define \( \nu t \) for \( t \in T \) such that if \( t > t_0 = \min T, \nu t_0 = \nu \); and if \( t > t_0, \nu t = \nu \mu t_0 t \). By the associative law we see that for \( t_1 < t_2 \in T, \nu t_2 = \nu t_1 \mu t_1 t_2 \).

Let \( \hat{T} \) denote the family of nonempty subsets of \( T \). For each \( \Lambda = \{ t_1 < \cdots < t_n \} \in \hat{T} \), we define \( \nu \Lambda = \nu t_1 \mu t_1 t_2 \otimes \cdots \otimes \mu t_{n-1} t_n \) as a probability measure on \( S^\Lambda \). We now show that the family \( \{ \nu \Lambda : \Lambda \in \hat{T} \} \) is consistent, i.e., for any \( \Lambda_1 \subset \Lambda_2, \pi^{\Lambda_2, \Lambda_1} \nu \Lambda_2 = \nu \Lambda_1 \), where \( \pi^{\Lambda_2, \Lambda_1} \) is the projection from \( S^{\Lambda_2} \) onto \( S^{\Lambda_1} \). It suffices to prove it in the case that \( |\Lambda_2 \setminus \Lambda_1| = 1 \). Write \( \Lambda_2 = \{ t_1 < \cdots < t_n \} \). Fix \( 1 \leq k \leq n \). We need to show that, if \( \Lambda_1 = \Lambda_2 \setminus \{ t_k \} \), then for any \( B \in \mathcal{S}^{n-1} \), with \( B_k \) defined by

\[
B_k = \{ (s_1, \ldots, s_n) \in S^n : (s_1, \ldots, s_{k-1}, s_{k+1}, \ldots, s_n) \in B \},
\]

we have \( \nu \Lambda_2 B_k = \nu \Lambda_1 B \). Recall that

\[
\nu \Lambda_2 B_k = \int \nu t_1 (ds_1) \int \mu t_1 t_2 (s_1, ds_2) \cdots \int \mu t_{n-1} t_n (s_{n-1}, ds_n) 1_{B_k} (s_1, \ldots, s_n)
\]

If \( k = n \),

\[
\nu \Lambda_2 B_n = \int \nu t_1 (ds_1) \cdots \mu t_{n-2} t_{n-1} (s_{n-2}, ds_{n-1}) \mu t_{n-1} t_n (s_{n-1}, ds_n) 1_B (s_1, \ldots, s_n)
\]

\[
= \int \nu t_1 (ds_1) \cdots \mu t_{n-2} t_{n-1} (s_{n-2}, ds_{n-1}) 1_B (s_1, \ldots, s_{n-1}) = \nu \Lambda_1 B.
\]

If \( k = 1 \), using \( \nu t_1 \mu t_1 t_2 = \mu t_2 \), we get

\[
\nu \Lambda_2 B_1 = \int \nu t_1 (ds_1) \int \mu t_1 t_2 (s_1, ds_2) \cdots \mu t_{n-1} t_n (s_{n-1}, ds_n) 1_B (s_2, \ldots, s_n)
\]
such that for any \( \Lambda \in \text{homogeneous transition kernels} \) is said to be space-homogeneous. We say that an \( \mu \) and we say that the kernel \( \mu(x, \cdot) = \mu(B - x) \). A kernel \( \mu \) on \( S \) is called homogeneous if there is a probability measure \( \nu \) on \( S \) such that

\[
\mu(x, \cdot) = x + \nu, \quad x \in S,
\]

and we say that the kernel \( \mu \) is induced by the measure \( \nu \). An \( S \)-valued Markov process with homogeneous transition kernels is said to be space-homogeneous. We say that an \( S \)-valued
process $X$ has independent increments if for any times $t_0 \leq \cdots \leq t_n$, $X_{t_0}$ and the increments $X_{t_k} - X_{t_{k-1}}$, $1 \leq k \leq n$, are mutually independent. Given a filtration $\mathcal{F}$ on $T$, an $\mathcal{F}$-adapted process $X$ is said to have $\mathcal{F}$-independent increments if for any $s \leq t \in T$, $(X_t - X_s) \in \mathcal{F}_s$. The latter condition is stronger because it implies that, for $t_0 \leq \cdots \leq t_n$, $(X_{t_0}, X_{t_j} - X_{t_{j-1}}, 1 \leq j \leq k - 1) \in \mathcal{F}_k$. For any $1 \leq k \leq n$.

**Proposition 7.5.** An $S$-valued process $X$ on $T$ is a space-homogeneous $\mathcal{F}$-Markov process if and only if it has $\mathcal{F}$-independent increments. Moreover, for each $s \leq t \in T$, the transition kernel $\mu_{s,t}$ is induced by the measure $\nu_{s,t} = \text{Law}(X_t - X_s)$, and the family $\nu_{s,t}$ satisfies if that $t_0 \leq t_1 \leq \cdots \leq t_n \in T$, then $\nu_{t_0,t_n} = \nu_{t_0,t_1} \ast \nu_{t_1,t_2} \ast \cdots \ast \nu_{t_{n-1},t_n}$.

**Proof.** First suppose $X$ has $\mathcal{F}$-independent increments. Let $t \leq u \in T$. From $X_u - X_t \in \mathcal{F}_t$, we get $\text{Law}(X_u - X_t|\mathcal{F}_t) = \text{Law}(X_u - X_t)$. Since $X_t$ is $\mathcal{F}_t$-measurable, we then get $\text{Law}(X_u - X_t) = X_t + \text{Law}(X_u - X_t)$. So we find that $X_t$ is an $\mathcal{F}$-Markov process with the transition kernel $\mu_{t,u}$ being the homogeneous kernel induced by $\text{Law}(X_u - X_t)$.

Next suppose $X$ is a space-homogeneous $\mathcal{F}$-Markov process with transition kernel $\mu_{t,u}$. Let $t \leq u \in T$. There is a probability measure $\nu_{t,u}$ on $S$ such that $\text{Law}(X_t|\mathcal{F}_t) = \mu_{t,u}(X_t, \cdot) = X_t + \nu_{t,u}$. Then we get $\text{Law}(X_u - X_t|\mathcal{F}_t) = \nu_{t,u}$. Since $\nu_{t,u}$ is a constant measure, we get $X_u - X_t \in \mathcal{F}_t$. So $X$ has $\mathcal{F}$-independent increments.

Finally, if $t_0 \leq t_1 \leq \cdots \leq t_n \in T$, then since $X_{t_k} - X_{t_{k-1}}$, $1 \leq k \leq n$, are independent, we get $\nu_{t_0,t_n} = \nu_{t_0,t_1} \cdots \nu_{t_{n-1},t_n}$.

For a family of homogeneous kernels $\mu_{t,u}$ induced by the measures $\nu_{t,u}$, $t < u \in T$, the Chapman-Kolmogorov relation is equivalent to that $\nu_{s,u} = \nu_{s,t} \ast \nu_{t,u}$ for $s < t < u \in T$.

In the case $T = \mathbb{R}_+$ or $\mathbb{Z}_+$, we define time-homogeneous Markov process. A Markov process with transition kernels $\mu_{s,t}$, $s < t \in T$, is called time-homogeneous if there is a family of kernels $\mu_t$, $t \in T$, on $S$, such that $\mu_{s,t} = \mu_{t-s}$ for every $s < t \in T$. This case, the Chapman-Kolmogorov relation is equivalent to that $\mu_{s,t} = \mu_{s+t}$, $\forall s,t \in T$. (8.3)

We call the family $\mu_t : t \in T$ satisfying (8.3) a semigroup. If each $\mu_t$ has mean zero, then $X$ is a martingale because $\mathbb{E}[X_u - X_t|\mathcal{F}_t] = \mathbb{E}[X_u - X_t] = \int x \mu_{u-t}(dx) = 0$ for $u \geq t$.

If a time-homogeneous Markov process is also space-homogeneous, then the kernels $\mu_t$, $t \in T$, are induced by probability measures $\nu_t$, $t \in T$, on $S$, and the Chapman-Kolmogorov relation is equivalent to that $\nu_s \ast \nu_t = \nu_{s+t}$, $\forall s,t \in T$. (8.4)

On the other hand, if the family $\nu_t$, $t \geq 0$, satisfies the above equality, by Theorem 7.4 we may then construct a space-homogeneous and time-homogeneous Markov process on $T$ with transition kernels $\mu_{s,t}(x, \cdot) = x + \nu_{t-s}$.

We have two families of probability measures $\nu_t : t \geq 0$ on $\mathbb{R}$ that satisfy (8.4) with $T = \mathbb{R}_+$. One is $\nu_t = \mathcal{N}(0, t)$, the normal distribution with mean 0 and variance $t$, $t \geq 0$, and the corresponding Markov process is a Brownian motion. Since the $\nu_t$ all have mean zero, a
Brownian motion is a martingale. A Brownian motion has a continuous version. The other example is \( \nu_t = \text{Pois}(t) \), the Poisson distribution with parameter \( t, t \geq 0 \), and the corresponding Markov process is a Poisson process, which takes integer values and has an rcll version.

Fix a semigroup of kernels \( \mu_t, t \in T \), on \( S \). For each probability measure \( \nu \) on \( S \), there is a canonical process \( X \) with initial distribution \( \mu \) and transition kernels \( \mu_{s,t} = \mu_{t-s}, s \leq t \). We use \( \mathbb{P}_\nu \) to denote the law of such \( X \), which is a probability measure on \( S^T \). In the case that \( \nu = \delta_x \) for \( x \in S \), we write \( \mathbb{P}_x \) for \( \mathbb{P}_{\delta_x} \).

**Lemma 7.7.** The measures \( \mathbb{P}_x, x \in S \), form a probability kernel from \( S \) to \( S^T \), and for any probability measure \( \nu \) on \( S \), \( \mathbb{P}_\nu = \mu \mathbb{P}_\nu \), i.e.,

\[
\mathbb{P}_\nu A = \int (\mathbb{P}_x A) \nu(dx), \quad \forall A \in \mathbb{S}^T.
\]

This lemma means that we may view \( \mathbb{P}_\nu \) as a mixture of \( \mathbb{P}_x, x \in S \).

**Proof.** Both the measurability of \( x \mapsto \mathbb{P}_x A \) and the displayed formula are obvious for cylinder sets of the form \( A = \pi^{-1}_A B \) for a finite set \( \Lambda \subset T \). The general case follows by a monotone class argument.

For \( t \in T \), define \( \theta_t : S^T \to S^T \) by \( (\theta_t \omega)_s = \theta_{t+s}, s \in T \). If \( X \) is a process on \( T \), then \( \theta_t X \) is the process \( X_{t+} \), i.e., the part of \( X \) after \( t \).

**Proposition 7.9** (Strong Markov Property). Fix a time-homogeneous Markov process \( X \) on \( T = \mathbb{R}_+ \) or \( \mathbb{Z}_+ \), and let \( \tau \) be a stopping time taking countably many values. Then a.s. on \( \{ \tau < \infty \} \), \( \text{Law}(\theta_\tau X|F_\tau) = \mathbb{P}_{X_\tau} \). Here we understand \( \mathbb{P}_{X_\tau} \) as the composition of the kernel \( \mathbb{P} \) with the map \( X_\tau \).

**Proof.** We first assume that \( \tau \) is a deterministic time \( t_0 \). For sets of the form \( A = \pi^{-1}_{\{t_1<\cdots<t_n\}} B \), by Proposition 7.2 and time-homogeneity,

\[
\mathbb{P}[\theta_{t_0} X \in A|F_{t_0}] = \mathbb{P}[(X_{t_0+t_1}, \ldots, X_{t_0+t_n}) \in B|F_{t_0}]
\]

\[
= (\mu_{t_1} \otimes \mu_{t_2-t_1} \otimes \cdots \otimes \mu_{t_n-t_{n-1}})(X_{t_0}, B) = \mathbb{P}_{X_{t_0}} A.
\]

By a monotone class argument, the above formula holds for any \( A \in \mathbb{S}^T \). So we get

\[
\text{Law}(\theta_{t_0} X|F_{t_0}) = \mathbb{P}_{X_{t_0}}.
\]

In the general case, suppose \( \tau \) takes values in the countable set \( C \). Then for any \( t \in C \setminus \{ \infty \} \), by Lemma 6.1, \( F_\tau \) agrees with \( F_t \) on \( \{ \tau = t \} \); and by Lemma 5.2, \( \text{Law}(\theta_{t_0} X|F_\tau) \) agrees with \( \text{Law}(\theta_{t_0} X|F_t) \) on \( \{ \tau = t \} \), which is \( \mathbb{P}_{X_t} \). So for each \( t \in C \setminus \{ \infty \} \), \( \text{Law}(\theta_{t_0} X|F_\tau) = \mathbb{P}_{X_t} = \mathbb{P}_{X_\tau} \) on \( \{ \tau = t \} \). Since \( C \) is countable and \( \{ \tau < \infty \} = \bigcup t \in C \{ \tau = t \} \), we arrive at the conclusion.

We say that a probability measure \( \nu \) is invariant for the semigroup \( \mu_t, t \in T \), if \( \nu \mu_t = \nu \) for every \( t \in T \). A process \( X \) on \( T \) is said to be stationary if for all \( t \in T \), \( \theta_t X \overset{d}{=} X \).
Lemma 7.11. Let $X$ be a time-homogeneous Markov process on $T$ with transition kernels $(\mu_t)$ and initial distribution $\nu$. Then $X$ is stationary iff $\nu$ is invariant for $(\mu_t)$.

Proof. If $X$ is stationary, then for any $t \in T$, 
$$\nu \mu_t = \nu = \text{Law}(X_t) = \text{Law}(\theta_t X_0) = \text{Law}(X_0) = \nu.$$ 
So $\nu$ is invariant for $(\mu_t)$. On the other hand, suppose $\nu$ is invariant for $(\mu_t)$. Then $\text{Law}(X_t) = \nu_t = \nu \mu_t = \nu$ for any $t \in T$. By Proposition 7.2 and time-homogeneity, for any $t_1 < \cdots < t_n \in T$ and $t_0 \in T$,
$$\text{Law}(X_{t_0+t_1}, \ldots, X_{t_0+t_n}) = \nu_{t_0+t} \otimes \mu_{t_0-t_0} \otimes \cdots \otimes \mu_{t_n-t_{n-1}} = \nu_{t_0} \otimes \mu_{t_1-t_0} \otimes \cdots \otimes \mu_{t_n-t_{n-1}} = \text{Law}(X_{t_1}, \ldots, X_{t_n}).$$
By a monotone class argument, we get $\theta_{t_0} X \overset{d}{=} X$. \hfill \qed

For a time-homogeneous Markov processes, if $T = \mathbb{R}_+$, it is called continuous-time; if $T = \mathbb{Z}_+$, it is called discrete-time. In the latter case, the family $\mu_n$, $n \in \mathbb{Z}_+$, are determined by the single kernel $\mu_1$ as $\mu_n = \mu_1 \cdots \mu_1$. When $S$ is countable, it is called discrete-state or a Markov chain.

From now on, let $X = (X_t)_{n \geq 0}$ be a discrete-time discrete-state Markov process. The transition kernels $\mu_n$ can be expressed by the square matrix $p^n$ indexed by $S$, where 
$$p^n_{x,y} = \mu_n(x, \{y\}), \quad x, y \in S.$$ 
The equality $\mu_n \mu_m = \mu_{n+m}$ becomes the equality of matrix product: $p^n p^m = p^{n+m}$, i.e., $p^{n+m}_{x,y} = \sum_{z \in S} p^n_{x,z} p^m_{z,y}$. When $n = 0$, $p^n$ is the identity matrix.

Let $y \in S$. We consider the sequence of successive visits to $y$. Define $\tau^0_y = 0$. When $\tau^n_y$ is defined, we define $\tau^{n+1}_y$ to be the first $t > \tau^n_y$ such that $X_t = y$. When such $t$ does not exist, we define $\tau^{n+1}_y = \infty$. Then we get an increasing sequence of stopping times $(\tau^n_y)_{n \geq 0}$. We define the occupation times
$$\kappa_y = \sup\{n : \tau^n_y < \infty\} = \sum_{n=1}^{\infty} 1\{X_{\tau^n_y} = y\}, \quad y \in S.$$ 
We define the hitting probabilities:
$$r_{x,y} = \mathbb{P}_x[\tau^1_y < \infty] = \mathbb{P}_x[\kappa_y \geq 1], \quad x, y \in S.$$ 

Proposition 7.12. For any $x, y \in S$ and $n \in \mathbb{N}$,
$$\mathbb{P}_x[\kappa_y \geq n] = \mathbb{P}_x[\tau^n_y < \infty] = r_{x,y} r^n_{y,y} - 1, \quad (8.5)$$
$$\mathbb{E}_x[\kappa_y] = \frac{r_{x,y}}{1 - r_{y,y}}. \quad (8.6)$$
Here if $r_{y,y} = 1$, then the fractal is understood as $\infty$ if $r_{x,y} > 0$, and 0 if $r_{x,y} = 0$. 

93
Proof. By Strong Markov property, conditionally on \( F^y_0 \), on the event \( \{ \tau^n_y < \infty \} \), the conditional law of the process \( X^y_{\tau^n_y} \) is \( P_y \). We observe that \( \tau^n_y + 1 - \tau^n_y \) agrees with \( \tau^n_y \) for the process \( X_{\tau^n_y} \). Thus,

\[
P_x[\tau^n_y + 1 < \infty | F^y_0, \tau^n_y < \infty] = P_x[\tau^n_y + 1 - \tau^n_y < \infty | F^y_0, \tau^n_y < \infty] = P_y[\tau^n_y < \infty] = r_{y,y}.
\]

Integrating this formula, we get

\[
P_x[\tau^n_y < \infty | F^y_0] = P_x[\tau^n_y < \infty]r_{y,y}, \quad n \geq 1.
\]

Since \( P_x[\tau^n_y < \infty] = r_{x,y} \), we get (8.5) by induction. Since \( E_x[\kappa_y] = \sum_{n=1}^{\infty} P_x[\kappa_y \geq n] \), summing (8.5) over \( n \in \mathbb{N} \), we get (8.6).

For \( x = y \), we get \( P_y[\kappa_y \geq n] = r^n_{y,y}, \ n \in \mathbb{N} \). If \( r_{y,y} = 1 \), then \( P_y \)-a.s. \( \kappa_y = \infty \), and we say that the state \( y \) is recurrent. If \( r_{y,y} < 1 \), then \( P_y \)-a.s. \( \kappa_y < \infty \), and we say that the state \( y \) is transient.

**Proposition 7.13.** If an invariant distribution \( \nu \) exists, then any state \( x \) with \( \nu\{x\} > 0 \) is recurrent.

**Proof.** By the invariance of \( \nu \),

\[
0 < \nu\{x\} = \sum_{y \in S} \nu\{y\} p^n_{y,x}.
\]

Thus, by Proposition 7.12,

\[
\infty = \sum_{n=1}^{\infty} \sum_{y \in S} \nu\{y\} p^n_{y,x} = \sum_{y \in S} \nu\{y\} \sum_{n=1}^{\infty} p^n_{y,x} = \sum_{y \in S} \nu\{y\} E_y[\kappa_x] = \sum_{y \in S} \nu\{y\} r_{y,x} \frac{\nu\{y\}}{1 - r_{x,x}} \leq \frac{1}{1 - r_{x,x}}.
\]

Then we must have \( r_{x,x} = 1 \), and so \( x \) is recurrent.

The period \( d_x \) of a state \( x \) is defined as the greatest common divisor of the set \( \{ n \in \mathbb{N} ; p^n_{x,x} > 0 \} \), and we say that \( x \) is aperiodic if \( d_x = 1 \). When the set of \( n \) is empty, the period is understood as \( \infty \).

**Proposition 7.14.** If \( x \in S \) has period \( d < \infty \), then \( p^{nd}_{x,x} > 0 \) for all but finitely many \( n \).

**Proof.** Let \( F = \{ n \in \mathbb{N} : p^{nd}_{x,x} > 0 \} \). If \( n, m \in F \), then from

\[
p^{(n+m)d}_{x,x} = \sum_{y \in S} p^{nd}_{x,y} p^{md}_{y,x} \geq p^{nd}_{x,x} p^{md}_{x,x} > 0,
\]

we get \( n+m \in F \). So \((F, +)\) is a semigroup. From the definition of the period, \( F \) has the greatest common divisor 1. Thus, the group generated by \( F \) is \( \mathbb{Z} \). Thus, there exist \( n_1, \ldots, n_k \in F \) and \( z_1, \ldots, z_k \in \mathbb{Z} \) such that \( \sum_j z_j n_j = 1 \). Let \( m = n_1 \sum_j |z_j| n_j \). Any \( n \geq m \) can be expressed as \( n = m + hn_1 + r \), where \( h \in \mathbb{Z}_+ \) and \( r \in \{0, \ldots, n_1 - 1\} \). Then we have

\[
n = hn_1 + m + r = hn_1 + n_1 \sum_j |z_j| n_j + r(\sum_j z_j n_j) = hn_1 + \sum_j n_j(|z_j n_1 + z_j r) \in F.
\]
Suppose $X$ starts from a recurrent state $x$. Then $X$ visits $x$ at the times $0 = \tau_x^0 < \tau_x^1 < \tau_x^2 < \cdots$, which are all finite. The successive excursions of $X$ from $x$ are processes $Y^n$, $n \in \mathbb{Z}_+$, of random finite lifetime, given by

$$Y^n = X_{\tau^n_x + t}, \quad 0 \leq t \leq \tau^n_{x+1} - \tau^n_x.$$ 

Note that each $Y^n$ starts from $x$ and ends at $x$. Conversely, we may construct $X$ from $(Y^n)$. First, since the lifetime of $Y^n$ equals $\tau^n_{x+1} - \tau^n_x$, we can recover all $\tau^n_x$ for $X$. Second, when $\tau^n_x$ is known, we may use $Y^n$ to recover the path of $X$ restricted to $[\tau^n_x, \tau^n_{x+1}]$.

**Proposition 7.15** (simplified version). The processes $Y^0, Y^1, Y^2, \ldots$ are independent with identical distribution.

**Proof.** Fix $n \in \mathbb{N}$. By strong Markov property, conditional on $\mathcal{F}_{\tau^n_x}$, the conditional law of the process $X_{\tau^n_x+}$ is the same as the unconditional law of $X$. Thus, $X_{\tau^n_x+}$ has the same law as $X$, and is independent of $\mathcal{F}_{\tau^n_x}$. Since $\tau^n_{x+1} - \tau^n_x$ is the first $t \geq 1$ such that $X_{\tau^n_x+t} = x$, and $Y^n = X_{\tau^n_x+}[0, \tau^n_{x+1}-\tau^n_x]$, we see that $Y^n \parallel \mathcal{F}_{\tau^n_x}$, and has the same law as $Y_0$. So all $Y^n$ have the same law. Since $Y^n$ concerns only the values of $X$ before $\tau^n_{x+1}$, we see that $Y^n$ is $\mathcal{F}_{\tau^n_{x+1}}$-measurable. From $Y^n \parallel \mathcal{F}_{\tau^n_x}$, we then know $Y^n \parallel (Y^k : 0 \leq k \leq n-1)$ for all $n \in \mathbb{N}$, which implies that $Y^0, Y^1, Y^2, \ldots$ are independent. \hfill $\square$

Recall that $r_{x,y} = \mathbb{P}_x[\tau_1^y < \infty]$.

**Lemma 7.17.** Let $x \in S$ be recurrent, and define $C_x = \{y \in S; r_{x,y} > 0\}$. Then $r_{y,z} = 1$ for all $y, z \in C_x$, and all states in $C_x$ are recurrent.

**Proof.** Suppose $X$ starts from $x$. Let $y \in C_x$. By the strong Markov property, conditionally on $\mathcal{F}_{\tau_y^x}$ and the event that $\tau_y^x < \infty$, the probability that $X$ returns to $x$ after $\tau_y^x$ at some finite time equals $r_{y,x}$. Thus the probability that $X$ visits $y$ and then returns to $x$ is $r_{x,y}r_{y,x}$. Since $x$ is recurrent, this probability is just $r_{x,y}$. Since $r_{x,y} > 0$, we get $r_{y,x} = 1$. Since $r_{x,y}, r_{y,x} > 0$, there are $m, n \in \mathbb{N}$ such that $p_{x,y}^n, p_{y,x}^m > 0$. Then we have

$$\mathbb{E}_y[\kappa_y] \geq \sum_{k=1}^{\infty} \mathbb{P}_y[X_k = y] \geq \sum_{k=1}^{\infty} p_{y,y}^k \geq \sum_{s=1}^{\infty} \sum_{z \in S} \sum_{w \in S} p_{y,z}^n p_{z,w}^m p_{w,y} = \sum_{s=1}^{\infty} \sum_{z \in S} \sum_{w \in S} p_{y,z}^n p_{z,w}^m \mathbb{E}_z[\kappa_y] = \infty.$$

Thus, $y$ is also recurrent. Since $r_{y,x} = 1$, we have $x \in C_y$. From the above result we get $r_{x,y} = 1$. Let $y, z \in C_x$. From $r_{y,x} = r_{x,z} = 1$ and the strong Markov property, we know that, if $X$ starts from $y$, then it visits $x$, and then visits $z$ after that time. So we get $r_{y,z} = 1$. \hfill $\square$

We say that $X$ is irreducible if $r_{x,y} > 0$ for any $x, y \in S$.

**Proposition 7.16.** Let $X$ be irreducible. Then
(i) the states are either all recurrent or all transient;

(ii) all states have the same period;

(iii) if $\nu$ is invariant, then $\nu\{x\} > 0$ for all $x \in S$.

If all states are recurrent/transient, then we say that $X$ is recurrent/transient.

Proof. (i) By Lemma 7.17, if one state $x$ is recurrent, then all states are recurrent since $C_x = S$.

(ii) For any $x, y \in S$, choose $n, m \in \mathbb{N}$ with $p^n_{x,y}, p^n_{y,x} > 0$. Then for any $h \geq 0$,

$$p^{n+h+m}_{y,y} = \sum_{z \in S} \sum_{w \in S} p^n_{y,z} p^h_{z,w} p^m_{w,y} \geq p^n_{y,x} p^h_{x,x} p^m_{x,y}.$$  

For $h = 0$, we get $p^{n+m}_{y,y} > 0$. So $d_y(m+n)$. In general, $p^h_{x,x} > 0$ implies that $p^{n+h+m}_{y,y} > 0$, and so $d_y > h$. So we get $d_y | d_x$. Thus, $d_x = d_y$.

(iii) Fix $x \in S$. Choose $y \in S$ with $\nu\{y\} > 0$ and $n \in \mathbb{N}$ such that $p^n_{y,x} > 0$. By invariance of $\nu$, we have

$$\nu\{x\} = \sum_{z \in S} \nu\{z\} p^n_{x,z} \geq \nu\{y\} p^n_{y,x} > 0.$$  

We may now state the basic ergodic theorem for irreducible Markov chains. Recall that for any signed measure $\mu$, its total variation is $\|\mu\|_{TV} = 2 \sup_A |\mu_A|$. If $X$ and $Y$ are two random elements with laws $\mu$ and $\nu$, then $\|\mu - \nu\|_{TV} \leq 2P[X \neq Y]$.

**Theorem 7.18.** Let $X$ be irreducible and aperiodic with state space $I$. Then exactly one of these conditions holds:

(i) There exists a unique invariant distribution $\nu$; furthermore, $\nu\{i\} > 0$ for all $i \in I$, and

$$\lim_{n \to \infty} \|P_{\mu} \circ \theta^{-1}_n - P_{\nu}\|_{TV} = 0. \quad (8.7)$$

(ii) No invariant distribution exists, and

$$\lim_{n \to \infty} p^n_{i,j} = 0, \quad \forall i, j \in I. \quad (8.8)$$

If $X$ satisfies (i), then it is recurrent because for any $x \in S$, from (8.7) we know that $p^n_{x,x} \to \nu\{x\} > 0$, which implies that $E_x[\kappa_x] = \sum_{n=1}^{\infty} p^n_{x,x} = \infty$. In this case we say that $X$ is positive recurrent. If $X$ satisfies (ii), it may be recurrent or transient. If it is recurrent, then we say that $X$ is null recurrent.
Lemma 7.19. Let $X$ and $Y$ be independent Markov chains on some countable state spaces $I$ and $J$, with transition matrices $(p_{i,i'})$ and $(q_{j,j'})$, respectively. Then the pair $(X,Y)$ is again Markov with transition matrices $r^{n}_{(i,j),(i',j')}$, where $r^{n}_{(i,j),(i',j')} = p^{n}_{i,i'} q^{n}_{j,j'}$. If $X$ and $Y$ are irreducible and aperiodic, then so is $(X,Y)$, and in that case $(X,Y)$ is recurrent whenever invariant distributions exist for both $X$ and $Y$.

Proof. Let $\mathcal{F}^X = (\mathcal{F}_n^X)$ and $\mathcal{F}^Y = (\mathcal{F}_n^Y)$ be the filtration induced by $X$ and $Y$, respectively. Define a new filtration $\mathcal{F}$ by $\mathcal{F}_n = \mathcal{F}_n^X \vee \mathcal{F}_n^Y$ for each $n \in \mathbb{Z}_+$. Then both $X$ and $Y$ are $\mathcal{F}$-adapted, and so is the joint process $(X,Y)$. Fix $m \geq n \in \mathbb{N}$. Then for every $i' \in I$ and $j' \in J$,

$$P[X_m = i' | \mathcal{F}_n^X] = p^{m-n}_{X_n,i'}, \quad P[Y_m = j' | \mathcal{F}_n^Y] = q^{m-n}_{Y_n,j'},$$

which is equivalent to that, for any $A \in \mathcal{F}_n^X$ and $B \in \mathcal{F}_n^Y$,

$$P[A \cap \{X_m = i'\}] = E[1_A p^{m-n}_{X_n,i'}], \quad P[B \cap \{Y_m = j'\}] = E[1_B q^{m-n}_{Y_n,j'}].$$

Since $X$ and $Y$ are independent, the above formula is further equivalent to

$$P[C \cap \{(X_m,Y_m) = (i',j')\}] = E[1_C p^{m-n}_{X_n,i'} q^{m-n}_{Y_n,j'}],$$

(8.9)

where $C = A \cap B$. By a monotone class argument, we see that (8.9) holds for any $C \in \mathcal{F}_n$. So we get

$$P[(X_m,Y_m) = (i',j') | \mathcal{F}_n] = p^{m-n}_{X_n,i'} q^{m-n}_{Y_n,j'} = r^{m-n}_{(X_n,Y_n),(i',j')}.$$  

So $(X,Y)$ is a Markov process with transition matrices $(r^{n}_{(i,j),(i',j')})$.

Suppose $X$ and $Y$ are irreducible and aperiodic. Fix $i, i' \in I$ and $j, j' \in J$. By Proposition 7.14, $p^{n}_{i,i'} > 0$ and $q^{n}_{j,j'} > 0$ for all but finitely many $n$. So $r^{n}_{(i,j),(i',j')} = p^{n}_{i,i'} q^{n}_{j,j'}$ for all but finitely many $n$. Thus, $(X,Y)$ is irreducible and aperiodic. Finally, suppose $\mu$ and $\nu$ are invariant distributions for $X$ and $Y$, respectively. Then $\mu \times \nu$ is an invariant distribution for $(X,Y)$ because for any $(i',j') \in I \times J$,

$$(\mu \times \nu)((i',j')) = \mu\{i'\} \nu\{j'\} = \left(\sum_{i \in I} \mu\{i\} p_{i,i'}\right) \left(\sum_{j \in J} \nu\{j\} q_{j,j'}\right)$$

$$= \sum_{(i,j) \in I \times J} (\mu \times \nu)\{(i,j)\} r^{n}_{(i,j),(i',j')}.$$  

By Proposition 7.16, $\mu\{i\}, \nu\{j\} > 0$ for any $i \in I$ and $j \in J$. So $(\mu \times \nu)\{(i,j)\} > 0$ for every $(i,j) \in I \times J$. By Proposition 7.13, $(X,Y)$ is recurrent. \hfill \square

Lemma 7.20. Let $I$ be a countable set. Let $\mu$ and $\nu$ be probability measures on $I$. Let $X$ and $Y$ be independent Markov chains on $I$ with the same transition matrices $(p^{n}_{i,i'})$ and initial distributions $\mu$ and $\nu$. Suppose that the Markov chain $(X,Y)$ on $I \times I$ is irreducible and recurrent. Then

$$\lim_{n \to \infty} \|P \circ \theta^{-1} - P \circ \theta^{-1}\|_{TV} = 0.$$  

(8.10)

97
Lemma 7.21 (Existence). In the setting of Theorem 7.18, if (8.8) fails, then an invariant distribution exists.

Proof. Assume that (8.8) fails. Then there are \(i_0, j_0 \in I\) such that \(\limsup p^n_{i_0, j_0} > 0\). By a diagonal argument, we may find a subsequence \(n' \subset \mathbb{N}\) such that for any \(j \in I\), \(p^n_{i_0, j}\) converges to some \(c_j \in [0, 1]\) along \(n'\). Moreover, we may choose \(n'\) such that \(c_{j_0} > 0\). Since \(\sum_j p^n_{i_0, j} = 1\) for every \(n\), by Fatou’s lemma, \(\sum_j c_j \leq 1\).

Let \(X\) and \(Y\) be independent with the transition matrix \(p\). By Lemma 7.19, \((X, Y)\) is an irreducible Markov chain on \(I^2\) with transition matrix \(r_{(i,j),(i',j')} = p_{i,i'}p_{j,j'}\). If \((X, Y)\) is transient, then for any \(i, j \in I\),

\[
\infty > \sum_{n=1}^{\infty} \mathbb{P}[(X_n, Y_n) = (j, j)] = \sum_{n=1}^{\infty} r^n_{(i,j),(j,j)} = \sum_{n=1}^{\infty} (p^n_{i,j})^2,
\]

which implies that (8.8) holds, which is a contradiction. So \((X, Y)\) is recurrent. By Lemma 7.20, for any \(i, j \in I\),

\[
|p^n_{i,j} - p^n_{i_0,j}| \leq \|\mathbb{P} \circ \theta_n^{-1} - \mathbb{P} \circ \theta_n^{-1}\|_{TV} \to 0.
\]

Since \(p^n_{i_0,j} \to c_j\) along \(n'\), we get \(p^n_{i,j} \to c_j\) along \(n'\) for all \(i, j \in I\). From the Chapman-Kolmogorov relation, we conclude that for any \(n\),

\[
\sum_{j \in I} p^n_{i,j} p^n_{j,k} = p^{n+1}_{i,k} = \sum_{j \in I} p^n_{i,j} p^n_{j,k}, \quad i, k \in I.
\]
Letting \( n \to \infty \) along \( N' \), by Fatou’s lemma we get
\[
\liminf_{N' \ni n \to \infty} \sum_{j \in I} p^{n}_{i,j} p_{j,k} \geq \sum_{j \in I} c_{j} p_{j,k};
\]
and by dominated convergence theorem we get
\[
\lim_{N' \ni n \to \infty} \sum_{j \in I} p^{n}_{i,j} p_{j,k} = \sum_{j \in I} c_{j} = c_{k}.
\]
Thus, \( c_{k} = \sum_{j \in I} c_{j} p_{j,k} \) for every \( k \in I \). Summing over \( k \), we get \( \sum_{k} c_{k} \) on both sides since \( \sum_{k} p_{j,k} = 1 \). So we must have \( c_{k} = \sum_{j \in I} c_{j} p_{j,k} \) for every \( k \in I \). Since \( c_{j_0} > 0 \), we get an invariant distribution \( \nu \) with \( \nu\{i\} = c_{j}/\sum_{i} c_{j}, i \in I \).

**Proof of Theorem 7.18.** If no invariant distribution exists, then (8.8) holds by Lemma 7.21. Now let \( \nu \) be an invariant distribution. By Proposition 7.16, \( \nu\{i\} > 0 \) for all \( i \in I \). By Lemma 7.19, the Markov chain \((X,Y)\) in Lemma 7.20 is irreducible and recurrent, so (8.10) holds for any initial distributions \( \mu \) and \( \nu \). If \( \nu \) is invariant, we get (8.7) since \( P_{\nu} \circ \theta_{n}^{-1} = P_{\nu} \) by Lemma 7.11. If \( \nu' \) is also invariant, then (8.7) yields \( P_{\nu'} = P_{\nu} \), and so \( \nu' = \nu \).

**Theorem 7.22.** For a Markov chain on \( I \) and states \( i,j \in J \) with \( j \) aperiodic, we have
\[
\lim_{n \to \infty} p^{n}_{i,j} = \frac{P_{i}[\tau_{j} < \infty]}{E_{i}[\tau_{j}]}.
\]

**Proof.** First take \( i = j \). If \( j \) is transient, then \( p^{n}_{j,j} \to 0 \) and \( E_{j}\tau_{j} = \infty \). The equality holds trivially. Suppose \( j \) is recurrent. If \( X \) starts from \( j \), then it stays in \( C_{j} \), and the restriction of \( X \) to \( C_{j} \) is a recurrent Markov chain by Lemma 7.17. Since \( j \) is aperiodic, \( X|_{C_{j}} \) is aperiodic by Proposition 7.16. Thus, \( \lim_{n \to \infty} p^{n}_{j,j} \) converges by Theorem 7.18.

Define \( L(n) = \sum_{k=1}^{n} 1_{X_{k}=j} \), the number of times that \( X \) visits \( j \) before \( n \). Then \( L \) is increasing, \( L(0) = 0 \), and \( L(\tau_{j}^{n}) = n \). Since \( \tau_{j}^{n} - \tau_{j}^{n-1}, n \geq 1 \), are mutually independent, by the law of large numbers, a.s. \( \frac{\tau_{j}^{n}}{n} \to E_{j}\tau_{j} \). This statement holds even if \( E_{j}\tau_{j} = \infty \) because in that case for any \( M > 0 \), \( \tau_{j}^{n} \geq \sum_{k=1}^{n} \zeta_{k}^{M} \), where \( \zeta_{k}^{M} = M \wedge (\tau_{j}^{k} - \tau_{j}^{k-1}) \), and we then get \( \liminf \frac{\tau_{j}^{n}}{n} \geq E_{j}[\zeta_{1}^{M}] \). Letting \( M \to \infty \), we then get \( \frac{\tau_{j}^{n}}{n} \to \frac{1}{E_{j}\tau_{j}} \). Thus, \( P_{j}\text{-a.s.} \lim_{n \to \infty} \frac{L(n)}{n} \to \frac{1}{E_{j}\tau_{j}} \).

For any \( n \in \mathbb{Z}_{+} \), we may find \( m \in \mathbb{Z}_{+} \) such that \( \tau_{j}^{m} \leq n < \tau_{j}^{m+1} \). Then \( L(n) = m \) and \( \frac{L(n)}{n} = \frac{m}{\frac{1}{E_{j}\tau_{j}}} \). Since \( L(n) \leq n \), by dominated convergence theorem, \( \frac{1}{n} \sum_{k=1}^{n} p^{n}_{j,j} = \frac{1}{n} E_{j}L(n) \to \frac{1}{E_{j}\tau_{j}} \). So we get \( \lim_{n \to \infty} p^{n}_{j,j} = \frac{1}{E_{j}\tau_{j}} \).

Now let \( i \neq j \). Using the strong Markov property and dominated convergence, we get
\[
p^{n}_{i,j} = P_{i}[X_{n} = j] = P_{i}[\tau_{j}^{1} \leq n, X_{n} = j] = P_{i}[\tau_{j}^{1} \leq n, (\theta_{\tau_{j}^{1}} \circ X)_{n-\tau_{j}^{1}} = j]
\]
\[
= E_{i}[1\{\tau_{j}^{1} \leq n\} p^{n-\tau_{j}^{1}}_{j,j}] = E_{i}[\tau_{j}^{1} < \infty] \lim_{n \to \infty} p^{n}_{j,j} = \frac{P_{i}[\tau_{j} < \infty]}{E_{i}[\tau_{j}]}.
\]
